Producer Price Indexes

Data for 1992

Preface

This annual supplement to *Producer Price Indexes* presents monthly indexes and annual averages for 1992. Indexes shown in the supplement are not seasonally adjusted. The supplement also provides information on the relative importance of components at yearend.

In addition, this supplement contains a summary of the latest major weight

update to reflect 1987 shipment values. It also summarizes the major price developments during 1992. Information on routine changes in the sample for producer price indexes during 1992 can be found in the January 1992 and July 1992 issues of *Producer Price Indexes*.

Price Highlights, 1992

Prices received by domestic producers of finished goods moved up 1.6 percent from December 1991 to December 1992 after inching down 0.1 percent in calendar year 1991. Consumer food prices increased 1.6 percent in 1992, offsetting a decrease of about the same size a year earlier. The index for finished energy goods eased 0.3 percent lower after a decline of nearly 10 percent in 1991. Outside of the food and energy sectors, prices for finished goods advanced 2.0 percent, well below the 3.1-percent rise in 1991; this was the smallest increase for any calendar year since 1983.

At earlier stages of processing, the Intermediate Goods Price Index rose 1.0 percent in 1992 in the wake of a 2.6-percent decrease the year before. The Crude Goods Price Index increased 3.3 percent from December 1991 to December 1992 following a drop of 11.6 percent during the preceding year. Energy prices turned up modestly at both the intermediate and the crude levels after double-digit declines in 1991. Crude foodstuff prices also moved up after falling a year earlier. Industrial material prices turned up at both the intermediate and the crude stages of processing.

Prices for many items included in the PPI system were weaker in the second half of the year than in the first. The increase in the Finished Goods Price Index, for example, slowed from a seasonally adjusted annual rate of 2.6 percent in the first 6 months of 1992 to a rate of 0.5 percent in the last 6 months of the year. The so-called "core" or "underlying" rate of inflation (that is, finished goods other than foods and energy) reflected the same pattern, rising at an annual rate of 2.7 percent from December 1991 to June 1992 followed by a 1.0-percent rate of advance from June to December 1992. The index for finished energy goods, which had risen at an annual rate of 7.4 percent in the first 6 months of the year, fell at about the same pace in the second half. Consumer food prices, however, turned up from June to December after easing slightly lower in the preceding 6 months.

Industrial material prices also tended to be stronger in the first 6 months of 1992 than in the rest of the year. The index for intermediate materials less foods and energy edged up at a rate of 0.5 percent in the second half, less than the first-half rate of 1.8 percent. Prices for both durable and nondurable manufacturing materials turned down in the second half after first-half increases. The rise in the index for basic industrial materials (that is, crude nonfood materials less energy) slowed to a seasonally adjusted annual rate of 2.0 percent from June to December after climbing at a rate of about 10 percent in the preceding 6 months.

Although the recession that had begun in July 1990 had officially ended by the spring of 1991, the recovery for the rest of that year and through most of 1992 was uncharacteristically sluggish compared with previous periods of recovery. It was not until the end of 1992 that the gross domestic product reached the same level as it had attained just prior to the start of the recession.

Personal consumption expenditures on goods and services were restrained by the need to reduce the unusually high debt burdens saddling many consumers in the aftermath of intense borrowing during the 1980's. The failure of employment to rebound significantly during the recovery further served to hamper consumer spending. Nevertheless, consumer spending strengthened considerably in the second half, partly at the expense of savings. Capital investment plans were held in check by unused capacity in many sectors, partly because of growing capacity in a number of newly-industrializing countries. Export demand was less buoyant in 1992 than in other recent times, largely because many of our major trading partners were also struggling with recession or low growth. The housing sector was again relatively strong; however, the commercial construction sector remained depressed in the aftermath of serious overbuilding in the mid-1980's.

Inflation usually continues to decelerate even well after a recession ends because output normally expands at a faster pace than employment during the early stages of recovery. This results in sizable productivity gains and lower unit labor costs. The unusually slow growth in employment from the March 1991 trough of the recession through the end of 1992 amplified this tendency. This factor was particularly important for finished goods, since changes in labor costs are a more critical determinant of the rate of price change for goods at the later stages of processing than for less processed goods. Productivity for nonfarm businesses as a whole grew 2.7 percent in 1992, far better than the 0.5-percent rise measured in 1991 and the highest increase for any calendar year since 1972.

The weakness in prices for many kinds of industrial materials during 1992 was somewhat puzzling in historic perspective. These prices are usually considered a sensitive leading indicator of the status of the general economy. But while most other sensitive economic indicators were pointing towards a strengthening economy by the end of the year, material prices were often far stronger in the first half of the year than in the second.

Update of the Producer Price Index Weights

Effective with data for January 1992, the weights used to construct Producer Price Indexes (PPI) were updated to reflect 1987 shipment values of commodities. From January 1987 through December 1991, weights were based on 1982 shipment values. Most of the weight shifts reflected changes in the American economy during the 1982-87 period.

Weights for individual products in the PPI are based on shipment values of the commodity, as measured by the *Census of Manufactures* and other sources. For categories broader than individual products, indexes are calculated using weighted averages of the components. Weights at all levels of aggregation and detail are implicitly adjusted each month in accordance with relative monthly price changes; that is, groupings or items whose prices are rising faster than average automatically attain proportionately increased weight, while weights for other categories simultaneously decrease. Over a period of years, however, such implicitly adjusted weights may no longer reflect contemporary production patterns. Therefore, it is necessary to revise the PPI weight structure by updating shipment values through what is called a major weight revision. Because the *Census of Manufactures* is conducted every 5 years, PPI weights ideally should also be updated on a 5-year cycle.

This most recent major weight revision affected all PPI series derived from the commodity code system, including stage-of-processing indexes, durability of product indexes, and special commodity groupings. It did not affect the PPI series for the net output of selected industries and their products, whose weights are updated on an industry-by-industry basis as part of the periodic resampling

process; most of these industry weights already are based on 1987 shipment values. The proportional allocations of commodity series to the various stage-of-processing categories continue to be based on 1972 input-output data. In addition, previously released indexes were not revised and there was no break in continuity of the PPI.

Many of the weight increases for various commodity categories were a result of increased production for durable goods that are sensitive to the general business cycle to meet the rising demand which grew out of the recovery from the recessions of the early 1980's. For example, passenger cars accounted for about 5.6 percent of the total weight in the Finished Goods category before the weight revision but amounted to nearly 7.8 percent of Finished Goods after the revision. In contrast, some categories declined in relative importance. For example, crude petroleum's relative weight within Crude Goods decreased from about 18.7 percent before the weight revision to about 16.5 percent after the weight shift. This reflected the relatively increased use of foreign oil during the 1982-87 period at the expense of domestically-produced crude petroleum.

Relative importance data for components of Producer Price Indexes affected by this major weight revision as of December 1991 (the month in which the old and new weights were linked) were published in tables 10, 11, and 12 in *Producer Price Indexes Data for 1991*. For analysis of the economic factors underlying the PPI weight changes, see "Effect of Updated Weights on Producer Price Indexes," by Roger Burns, Harry Briggs, and William Thomas, in *Monthly Labor Review*, March 1993.

¹ Monthly data and annual averages have been revised to reflect the availability of late reports and corrections by respondents.

² Industry and product class indexes may include products not shown separately.

³ Not available.

n.e.c. = Not elsewhere classified.

mfp = Made from purchased materials.

n.s.k. = Not specified by kind.

Note: Indexes in this table are calculated by a revised methodology. See Technical Notes at the back of this publication. The annual average calculation method for the PPIR differs from that of the PPI (table 4). The PPIR method averages the unrounded monthly indexes, and also includes unpublished monthly data. Therefore, the annual averages may not agree with those computed by averaging the monthly indexes as shown above.

¹ Monthly data and annual averages have been revised to reflect the availability of late reports and corrections by respondents. Indexes in this table are derived from the primary product indexes in table 3 that are weighted using 1977 input/output relationships. These indexes only include inputs to construction which are produced by the mining and

manufacturing sectors of the economy, excluding capital equipment. Since they do not include labor or capital costs, these indexes should not be regarded as comprehensive measures of change in construction costs. See note on page 190 of *Producer Price Indexes Data for July 1986*.

¹ Monthly data and annual averages have been revised to reflect the availability of late reports and corrections by respondents. Indexes in this table are derived from the product indexes in table 3. These indexes are composed of the goods used by the industries in each of the industry stage of process output indexes as shown by the 1977

input/output relationships. These material inputs include only domestic material input and do not include any imported materials which may be used.

¹ The relative importance of a component represents its value weight that is allocated to a particular stage-of-processing (SOP) category—finished goods, intermediate materials, or crude materials—expressed as a percentage of the total weight of the SOP category. The "Revised" column shows relative importance figures for December 1992 based on 1987 shipment values from the *Census of Manufactures* and other sources, after the sample revision effective January 1993; the "Former" relative importance figures are for the same month before the revision.

sion of the index sample. Except for recodes, a dash in the "Former" column indicates that the series was introduced in January 1993 and a dash in the "Revised" column indicates that the series was discontinued as of January 1993. Groupings and subtotals may not add exactly to totals because of rounding differences. The value 0.000 represents either a percentage less than 0.0005 or a grouping newly introduced or deleted in January 1993 (if the 0.000 appears in the "Former" or "Revised" column, respectively).

¹ The relative importance of a component represents its value weight that is allocated to a particular stage-of-processing (SOP) category—finished goods, intermediate materials, or crude materials—expressed as a percentage of the total weight of the SOP category. The "Revised" column shows relative importance figures for December 1992 based on 1987 shipment values from the *Census of Manufactures* and other sources, after the sample revision effective January 1993; the "Former" relative importance figures are for the same month before the revision of the index sample.

Groupings and subtotals may not add exactly to totals because of rounding differences. The value 0.000 represents either a percentage less than 0.0005 or a grouping newly introduced or deleted in January 1993 (if the 0.000 appears in the "Former" or "Revised" column, respectively). Newly introduced or deleted groupings may be identified by referring to table 10.

¹ All relative importance figures in this table are expressed as a percentage of the all commodities index. The "Revised" column shows relative importance figures for December 1992 based on weights taken from 1987 shipment values from the *Census of Manufactures* and other sources, and reflects all sample revisions effective January 1993. The "Former" column provides relative importance figures for the same month based on weights taken from 1987 shipment values, before the January 1993 sample revisions. Except for recodes, a dash in the "Revised" column indicates a series that was discontinued as of January 1993, while a dash in the "Former" column indicates a series

introduced that same month. Subtotals may not add exactly to totals because of rounding differences. The value 0.000 represents a percentage less than 0.0005.

² The relative importance data for the three major SOP groupings—finished goods, intermediate materials, and crude materials—do not add up to 100.000 because they exclude the portion of goods allocated to government purchases and exports.

Technical Notes

Brief Explanation of Producer Price Indexes

Producer price indexes (PPI) measure average changes in prices received by domestic producers of commodities in all stages of processing. Most of the information used in calculating the indexes is obtained through the systematic sampling of nearly every industry in the manufacturing and mining sectors of the economy. The PPI program also includes some information from other sectors—agriculture, fishing, forestry, services, and gas and electricity. Because producer price indexes are designed to measure only the change in prices received for the output of domestic industries, imports are not included. The sample currently contains about 3,100 commodities and 75,000 quotations per month.

There are three primary systems of indexes within the PPI program: (1) Stage-of-processing indexes; (2) commodity indexes and; (3) indexes for the net output of industries and their products. The stage-of-processing structure (table 1) organizes products by class of buyer and degree of fabrication. The entire output of various industries is sampled to derive price indexes for the net output of industries and their products (table 3). The commodity structure (table 4) organizes products by similarity of end-use or material composition.

Within the stage-of-processing system, finished goods are commodities that will not undergo further processing and are ready for sale to the final demand user, either an individual consumer or business firm. Consumer foods include unprocessed foods such as eggs and fresh vegetables, as well as processed foods such as bakery products and meats. Other finished consumer goods include durable goods such as automobiles, household furniture, and appliances, and nondurable goods such as apparel and home heating oil. Capital equipment includes producer durable goods such as heavy motor trucks, tractors, and machine tools.

The stage-of-processing category for intermediate materials, supplies, and components consists partly of commodities that have been processed but require further processing. Examples of such semifinished goods include flour, cotton yarn, steel mill products, and lumber. The intermediate goods category also encompasses items that are physically complete but that are purchased by

business firms as inputs for their operations. Examples include diesel fuel, belts and belting, paper boxes, and fertilizers.

Crude materials for further processing are products entering the market for the

first time that have not been manufactured or fabricated and that are not sold directly to consumers. Crude foodstuffs and feedstuffs include items such as grains and livestock. Examples of crude nonfood materials include raw cotton, crude petroleum, coal, hides and skins, and iron and steel scrap.

The illustration shows examples of how products are classified by stage of processing.

Producer price indexes for the net output of industries and their products are grouped according to the Standard Industrial Classification (SIC) and the Census product code extension of the SIC. Industry price indexes are compatible with other economic time series organized by SIC codes, such as data on employment, wages, and productivity. Table 3 includes data for SIC industries and industry groups (2-, 3-, and 4-digit levels); indexes for Census product classes (5- and 6-digit levels), products (7-digit level), and more detailed subproducts (9-digit level); and, for some industries, indexes for other sources of revenue.

Indexes may be represented by one to three kinds of product indexes. Every industry has primary product indexes to show changes in prices received by establishments classified in the industry for products made primarily, but not always exclusively, within the industry. The industry classification of an establishment is determined by which products comprise a plurality of its total shipment value. In addition, some industries also may have secondary product indexes that show changes in prices received by establishments classified in the industry for products primary to some other industry. Finally, some industries have miscellaneous receipts indexes to show price changes in other sources of revenue received by establishments within the industry that are not derived from sales of their products, e.g., resales of purchased materials, or revenues from parking lots owned by a manufacturing plant.

Some product indexes published in table 3 correspond to 8-digit commodity indexes in table 4. In these cases, movement of the latter indexes are calculated on the basis of movements of their counterparts in table 3. Although most such indexes continue to be published in table 4 on a base period of 1982 = 100 or some later base, corresponding indexes in table 3 are published on a base of the month of their introduction. Even though index levels for corresponding items may differ, monthly percent changes will be identical. (See "Calculating Index Changes," below.)

Producer price indexes are based on selling prices reported by establishments of all sizes selected by probability sampling, with the probability of selection proportionate to size. Individual items and transaction terms from these firms are also chosen by probability proportionate to size. BLS strongly encourages cooperating companies to supply actual transaction prices at the time of shipment

to minimize the use of list prices. Prices are normally reported by mail questionnaire for the Tuesday of the week containing the 13th.

Price data are provided on a voluntary and confidential basis; no one but sworn BLS employees are allowed access to individual company price reports. The Bureau publishes price indexes instead of unit dollar prices. All producer price indexes are routinely subject to revision once, 4 months after original publication, to reflect the availability of late reports and corrections by respondents.

Net output values of shipments are used as weights for industry indexes. Net output values refer to the value of shipments from establishments in one industry to establishments classified in another industry. However, weights for commodity price indexes are based on gross shipment values, including shipment values between establishments within the same industry. As a result, broad commodity grouping indexes such as the all commodities index are affected by the multiple counting of price change at successive stages of processing, which can lead to exaggerated or misleading signals about inflation. Stage-of-processing indexes partially correct this defect, but industry indexes consistently correct for this at all levels of aggregation. Therefore, industry and stage-of-processing indexes are more appropriate than broad commodity groupings for economic analysis of general price trends. Weights for most traditional commodity groupings of the PPI, as well as all indexes (such as stage-of-processing indexes) calculated from traditional commodity groupings, currently reflect 1987 values of shipments as reported in the *Census of Manufactures* and other sources. From January 1987 through December 1991, PPI weights were derived from 1982 shipment values. Industry indexes, which are based on the SIC system, continue to be calculated with 1977 net output weights.

Effective with publication of January 1988 data, many important PPI series (including all stage-of-processing groupings and most commodity groups and individual items) were placed on a new reference base, 1982 = 100, to coincide with the reference year of shipment weights. From 1971 through 1987, the standard reference base for most PPI series was 1967 = 100. Except for rounding differences, the shift to the new reference base did not cause any changes to previously published percent changes for affected PPI series. (See "Calculating Index Changes," below.) The new reference base is not used for indexes with a base later than December 1981, nor for indexes for the net output of industries and their products.

Calculating Index Changes

Movements of price indexes from one month to another are usually expressed as percent changes rather than as changes in index points because index point changes are affected by the level of the index in relation to its base period, while percent changes are not. The box shows the computation of index point and percent changes.

<i>Index Point Change</i>	
Finished Goods Price Index	107.5
Less previous index	104.0
Equals index point change	3.5
<i>Index Percent Change</i>	
Index point change	3.5
Divided by the previous index	104.0
Equals	0.034
Results multiplied by 100	0.034 x 100
Equals percent change	3.5

Percent changes for 3-month and 6-month periods can be expressed as annual rates that are computed according to the standard formula for compound growth rates. These data indicate what the percent change would be if the rate for a given 3- or 6-month span were maintained for a 12-month period.

Each index measures price changes from a reference period which equals 100.0 (1982 or some later month). An increase of 5.5 percent from the reference period in the Finished Goods Price Index, for example, is shown as 105.5. This change can also be expressed in dollars as follows: "Prices received by domestic producers of a systematic sample of finished goods have risen from \$100 in 1982 to \$105.50 today." Likewise, a current index of 90.0 would indicate that prices received by producers of finished goods today are 10 percent lower than they were in 1982.

Seasonally Adjusted and Unadjusted Data

Because price data are used for different purposes by different groups, the Bureau of Labor Statistics publishes seasonally adjusted as well as unadjusted changes each month.

Seasonally adjusted data are preferred for analyzing general price trends in the economy because they eliminate the effect of changes that normally occur at about

the same time and in about the same magnitude every year—such as price movements resulting from normal weather patterns, regular production and marketing cycles, model changeovers, seasonal discounts, and holidays. For these reasons, seasonally adjusted data more clearly reveal underlying cyclical trends.

Unadjusted data are of primary interest to users who need information which can be related to actual dollar values of transactions. Individuals requiring this information include marketing specialists, purchasing agents, budget and cost analysts, contract specialists, and commodity traders. It is the unadjusted data that are generally cited in escalating long-term contracts such as purchasing agreements or real estate leases. (See *Escalation and Producer Price Indexes: A Guide for Contracting Parties*, BLS Report 807, 1991 edition, available on request from BLS.)

Seasonal factors used in computing seasonally adjusted indexes are derived from the X-11 Seasonal Adjustment Method. Annual updates replace the most recent 5 years of seasonal data, e.g., data from January 1983 through December 1987 were replaced at the beginning of 1988. Indexes for most broad commodity groupings and 8-digit individual commodities in table 4, as well as industry and Census product indexes in table 3, do not undergo the seasonal adjustment process and, therefore, are published only as unadjusted data.

Some indexes are adjusted directly, independently of the seasonal movements of other more detailed series comprising the category in question. This is the case for all indexes in table 4 which are adjusted, as well as for certain basic stage-of-processing categories in table 1. Seasonal movements for most stage-of-processing indexes are derived indirectly by the aggregate method, which combines seasonal movements of the basic stage-of-processing categories, and from a wide variety of food and certain other subproduct class (6-digit level) series.

Direct seasonal adjustment produces a more complete elimination of seasonal movements than the aggregative method does. However, the direct seasonal adjustment process does not yield figures that possess additive consistency. Thus, a seasonally adjusted index for a broad category that is directly adjusted may not be logically consistent with all seasonally adjusted indexes for its components. Seasonally adjusted data can also become problematic when previously stable and predictable timing patterns of pricing behaviour abruptly change. If the new timing pattern persists, the seasonal adjustment method will eventually reflect it adequately; if these patterns keep shifting, however, seasonally adjusted data will be chronically troublesome. This problem occurs relatively infrequently for farm and food-related products but has more often affected manufactured products such as automobiles and steel.
