By EDWARD F. DENISON

# Explanations of Declining Productivity Growth 

GGROWTH of American productivity was rapid by historical standards during most of the postwar period. But in the last half of the 1960 's the rate began to slacken. Until 1974 this slackening was not particularly disturbing from the standpoint of long-term growth. It was partly the consequence of short-term fluctuations in determinants of output that typically display irregular movements, chiefly a drop in the intensity of use of employed labor and capital from a peak reached in 1965-66. The remainder resulted from developments that were inevitable or even welcome. Transfer of surplus workers from farming to nonfarm jobs, in which they produce output of greater value, diminished as the pool of such labor approached exhaustion. The proportion of inexperienced workers among the employed was boosted by great increases in the working-age population under 25 years of age, a rising ratio of employment to population in the young age groups, and entry of many adult women into the labor force. Costs of regulations that the Government presumably felt had benefits in excess of their costs began to impinge upon productivity. This comfortable characterization of the
productivity slowdown is not applicable to more recent years. Beginning in 1974 the situation became disturbing and also puzzling. The productivity trend turned far more adverse, and the influences responsible for the slowdown prior to 1974 were no longer sufficient to explain the shortfall from the earlier trend. The major productivity seriesoutput per person employed, output per hour, and output per unit of inputall show much the same pattern of retardation.

The discussion in this article is organized by reference to output per person employed and the decline in its growth rate since 1973. The estimates cited refer to the nonresidential business sector, which makes up more than three-fourths of the whole economy. Output is measured by national income in constant (1972) prices. Employment is defined as the number of persons employed, full-time or part-time, during an average week. Wage and salary workers, the self-employed, and unpaid family workers are included. The average level of the series is based on the Current Population Survey, but for maximum consistency with the national income series its movement is
based mainly on establishment reports
In nonresidential business, national income per person employed (NIPPE) increased by an average of 2.4 percent a year during the quarter century from 1948 to 1973-a total of 82 percent over the period. It then dropped by a total of 5.6 percent from 1973 to 1975. Even after a recovery in 1976, NIPPE remained lower than 3 years before; its 1973-76 growth rate was -0.5 percent a year. The analysis of growth sources upon which this article draws has been carried only to 1976, but it is evident that slow productivity growth has characterized the entire period after 1973, continuing to the present time. In 1977 and 1978 NIPPE increased only enough to regain its 1973 level, so over the whole 5 -year period from 1973 to 1978 its growth rate was zero. The first half of 1979 was below 1973 (and 1978). Let me observe here that when I use adjectives such as "slow" or "retarded" to describe growth in recent periods, and when I refer to a growth rate as having declined, I mean to include situations in which the recent growth rate has actually been negative.

I have previously studied economic

This article discusses a wide range of suggested causes of the decline in the rate of productivity growth in recent years. It is the second Survey of Current Business article that presents portions of Mr. Denison's comprehensive study of this subject, which will be published by The Brookings Institution as Accounting for Slower Growth: The United States in the 1970s. The first article, which appeared in the January 1978 Survey, dealt with effects on output per unit of input of new requirements to protect the physical environment against pollution, increased requirements to protect the safety and health of employed persons, and a rise in dishonesty and crime.

Mr. Denison, who is now an Associate Director of the Bureau of Economic Analysis, was a Senior Fellow of The Brookings Institution when he wrote the forthcoming book. Financial support for the study was provided in part by National Science Foundation Grant 75-23131 to The Brookings Institution. Views expressed are the author's and should not be ascribed to the trustees, officers, or other staff members of the Institution or the Foundation or to the U.S. Department of Commerce.
growth in advanced countries by techniques that have become known as "growth accounting" or "sources of growth" analysis. Estimates resulting from such analysis were published for this country in my Accounting for United States Economic Growth, 19291969 (hereinafter cited as Accounting for Growth). ${ }^{1}$ They are revised and updated in a forthcoming book titled Accounting for Slower Economic Growth: The United States in the 1970s (hereinafter cited as Accounting for Slower Growth). ${ }^{2}$ Growth accounting views growth as the result of changes in a large number of determinants that govern the size of a nation's output. The contributions, positive or negative, that were made to the growth rate by changes in these determinants are estimated directly for as many determinants as is feasible. The combined contribution of the remaining determinants is obtained as a residual.

The directly estimated determinants of nonresidential business output accounted for almost all of the variation in the rate of growth of NIPPE within the period from 1948 to 1973. But they explain only part of the subsequent decline in this growth rate. The final chapter of the forthcoming book examines possible explanations for the remainder of the decline. That chapter is presented, with minor adaptations, as part 2 of this article.

To understand the discussion in part 2 , the reader must know what output determinants have been estimated directly; these determinants are not discussed in part 2 because they do not contribute to the unexplained portion of the decline in the growth rate of NIPPE. Part 1, which should be regarded as an introduction, provides that information; it describes briefly these determinants and their contributions.

## Part 1. Sources of Growth of National Income Per Person Employed

GROWTH of output may be obtained by using more labor and property resources in production or by increasing the output obtained from the same quantity of resources. In a table showing sources of growth of total output, the contributions made to the growth rate of output by changes in employment, working hours, and pertinent personal attributes of employed persons, by changes in the amount of capital, and by changes in the amount of land, would appear as contributions of total factor input, while the contributions of output per unit of input would include changes in the state of knowledge, the degree of misallocation of resources, the size of markets, and other conditions that alter the amount of output that is obtained from a given amount of input. In a table, such as table 1, that shows the sources of growth of output per person employed, employment disappears as a source of growth, and all other inputs-capital and land as well as labor characteristics-are measured on a per person-employed basis. Output per unit of input is the
same as for total output because the ratio of output to input is unchanged when both are divided by employment.

## Growth from 1948 to 1973

To consider recent changes, it is first necessary to know what the various determinants of output contributed to growth of NIPPE in the past. From 1948 to 1973 the growth rate of NIPPE was 2.43 percent a year. ${ }^{3}$ The first column of table 1 summarizes my estimates of the sources of its growth in that period.

Changes in average hours at work subtracted an estimated 0.24 percentage points from the growth rate in 1948-73. This is not an estimate of the growth rate of average hours, which was -0.50 percent, but an estimate of the net effect of changes in average working hours upon the growth rate of output. It allows for the fact that labor is only one, though by far the largest, type of factor input. In addition, it takes into account the probability that shorter hours for full-time workers have increased the work done in an hour by
lessening fatigue and absenteeism, so that the percentage decline in labor input is less than that in hours. Also, otherwise similar individuals are counted as the same amount of labor input whether they are nonfarm wage and salary workers, nonfarm self-employed and unpaid family workers, or farm workers, provided that each works the average full-time hours of persons of his or her own sex in the category in which he or she is employed. Consequently, the contribution of hours changes is not affected by that part of the decline in average hours that resulted from reductions in the proportions of workers in farming or nonfarm self-employment, categories with very long hours.
Hours worked by persons in different age-sex groups do not represent the same amount of labor input. If average hourly earnings in one such group are double those in another, an hour's work is considered, on the average, to represent twice as much labor input in the former as in the latter. Changes in agesex composition make a positive contribution when the proportion of total hours that are worked by persons in the highly weighted groups-particularly males 35 to 64 years of age-rises, as was the case from 1948 to 1954 , and a negative contribution when that proportion falls, as has been the case since 1954. Over the whole 1948-73 period changes in age-sex composition subtracted 0.17 percentage points from the growth rate.

Persons with different amounts of education also are regarded as providing different amounts of labor input. Their work is weighted in accordance with average earnings differentials between persons who differ only with respect to amount of education. For example, in recent years a full-time worker with 4 years of college is counted as 1.84 times as much labor as one with 8 years of elementary education. The contribution of education measures the amount by which output per worker has been raised by the upswing in the educational background of employed persons. The educational distribution of employed persons rose greatly, so the contribution of education was

1. Contributions to the growth rate shown in subsequent lines are restricted to effects upon output per unit of input.
2. Includes only gains resulting from the reallocation of labor out of farming and out of self-employment and unpaid family labor in small nonfarm enterprises.
3. Includes only the effects on output per unit of input of costs incurred to protect the physical environment and the safety and health of workers, and of costs of dishonesty and crime.
4. Obtained as a residual.

Source: Edward F. Denison, Accounting for Slower Economic Growth: The United States in the 1970s, The Brookings Institution, 1979, Table 7-3. (To be published)
positive and large, 0.52 percentage points. ${ }^{4}$

The contributions of capital and land result from changes in the amounts of inventories, nonresidential structures and equipment, and land used in nonresidential business per person employed. The main points to note are that dwellings and governmental assets are excluded, and that capital input is so defined and measured that changes in output that result from advances in the design of capital goods are classified as contributions of advances in knowledge, not of capital.

The contributions of capital and land do not reflect changes in the intensity of their utilization. Instead, a single estimate is made of the effect upon output per unit of input of changes in the intensity with which capital, land, and labor (as measured by hours at work) are utilized. That series is a component of the "irregular factors" line in table 1.

Inventories and fixed capital both increased more than employment from 1948 to 1973, so that capital input per person employed rose. The increase in the quantity of inventories per person employed contributed an estimated 0.10 percentage points to the growth rate of NIPPE, and the increase in nonresidential structures and equipment per person employed contributed 0.29 percentage points. The land available
per worker declined as employment increased. This subtracted an estimated 0.04 percentage points from the 1948-73 growth rate.

Improved allocation of resources contributed an estimated 0.37 percentage points to the growth rate. This estimate refers to gains in output from bringing the allocation of resources within the nonresidential business sector nearer to the allocation that would maximize output per unit of input. Only two types of changes in resource allocation are covered by this estimate. One is the reduction in the percentage of the labor used in nonresidential business that consists of surplus labor in farming. The other is the reduction in the percentage of labor that is misallocated to nonfarm self-employment and unpaid family labor in enterprises too small for efficiency.

The institutional and human environment within which business must operate has changed in several ways that adversely affect output per unit of input. The effect of three such changes has been estimated. New or strengthened governmental controls required business to divert from ordinary production to pollution abatement a growing share of the labor and capital that it employs, so that these resources are no longer available to produce measured output. Other controls have
similarly diverted labor and capital to the protection of worker safety and health. In addition, rising crime has forced business to divert resources to crime prevention, and thefts of merchandise have directly reduced measured output. Important changes in these conditions began only towards the end of the 1948-73 period, and they are estimated to have subtracted only 0.04 percentage points from the growth rate over that whole period.

Gains from economies of scale refer to the rise in output per unit of input that is made possible by changes in the size of the markets that business serves. Economies of scale are not limited to those internal to firms; specialization of all sorts, including larger production runs and larger transactions, is covered by my use of the term. Economies of scale are estimated to have contributed 0.41 percentage points to the 1948-73 growth rate, and thus to be an important growth source. It should be noted that I have measured the contributions of all other sources as if the economy were operating under constant returns to scale, so that to the definition of their contributions must be added the stipulation that the size of markets is taken as given.

The estimate of the effects of irregular factors upon output per unit of input covers three determinants. Two-the effect of weather upon farm output, and the effect of work stoppages-are rather minor, but the third is often important. This is the effect of changes in the intensity with which employed labor, capital, and land are used that result from fluctuations in demand. These changes are related to the business cycle, but swings in productivity usually run substantially ahead of those in total output or unemployment. The position was much less favorable to high output per unit of input in 1973 than in 1948, and irregular factors subtracted 0.18 percentage points from the 1948-73 growth rate.

The contribution of advances in knowledge and miscellaneous determinants is obtained, statistically, as a residual. As its title indicates, it has two main parts.

The contribution of advances in
knowledge is, conceptually, a comprehensive measure of the gains in measured output that result from the incorporation into production of new knowledge of any type-managerial and organizational as well as technolog-ical-regardless of the source of that knowledge, the way it is transmitted to those who can make use of it, or the way it is incorporated into production. The reference to "measured" output is important because of quality change. The introduction of new final products provides the user with a greater range of choice or enables him to meet his needs better with the same use of resources, but it does not, in general, contribute to growth as measured; it results in "noneconomic" or "unmeasured" quality change. In general, as a consequence, only the advances in knowledge that reduce the unit costs of final products already in existence contribute to measured growth.

The "miscellaneous determinants" portion of the title of this series refers to a large number of determinants that can be specified but whose effects have either been estimated at zero or not quantified. ${ }^{5}$ The effects of the determinants included are believed small, and as a group as likely to be favorable as unfavorable, in the 1948-73 period. ${ }^{6}$

The advance in knowledge was the largest source of increase in NIPPE from 1948 to 1973 unless I am altogether wrong in my judgment that miscellaneous determinents were not important in that period. The contribution of advances in knowledge and miscellaneous determinants is estimated at 1.41 percentage points in 1948-73.

In summary, important contributions to the growth of NIPPE in 1948-73 were made by advances in knowledge, increased education of employed persons, increased capital per worker, improved resource allocation, and economies of scale. Reductions in average hours of work and shifts in age-sex composition were the main negative factors.

## Change from 1948-73 to 1973-76

The growth rate of NIPPE fell from 2.43 percent in 1948-73 to -0.54 percent in 1973-76. This decline of nearly
3.0 percentage points occurred even though changes in three determinants were more favorable than in 1948-73. First, the contribution of education increased by 0.36 percentage points as the educational level of persons employed by business moved upward at an accelerated rate. Major factors were that government stopped absorbing a disproportionate part of the increase in
highly educated persons, and that the average age of adult workers declined. (Young adult workers have more education than older workers.) Second, the drag of a fixed quantity of land was a trifle less than in 1948-73 because employment increased less. Third, irregular factors were more favorable in 1976 than in 1973 and made a positive contribution to the 1973-76 growth rate,

## Nonresidential Business: Constant-Dollar National Income, Total and Per Person Employed, 1948-78, and Residual Series, 1948-76

whereas they reduced the 1948-73 rate. These determinants would, in themselves, have raised the growth rate by more than 0.6 percentage points.

Other sources for which specific estimates are made would, in themselves, have taken nearly 1.5 percentage points off the previous growth rate of NIPPE, an amount that is equal to three-fifths of the earlier rate. Six groups of sources contributed to this amount. An accelerated reduction in average hours was responsible for 0.30 percentage points, a faster shift in age-sex composition for 0.08 points, and a slower increase in capital per worker for 0.12 points, with both inventories and structures and equipment contributing to the last amount. Gains from the reallocation out of farming and nonfarm self-employment both disappeared, and this reduced the growth rate by 0.38 points. The three specified types of changes in the legal and human environment in which business operates cut the earlier growth rate of NIPPE by 0.40 points. ${ }^{7}$ Finally, gains from economies of scale were down by 0.17 points as growth of the economy slackened; this is a very crude estimate but there is no doubt that there was an appreciable reduction.

Almost 2.2 percentage points of the drop in the growth rate of NIPPE remain in the residual series for advances in knowledge and miscellaneous determinants. The contribution of the residual fell from 1.41 percentage points in 1948-73 to -0.75 percentage points in 1973-76. After rising steadily until 1973, the series dropped sharply in 1974 and 1975 , then in 1976 made a normal gain from the lower level.

Chart 1 helps to make clear how extraordinary the period since 1973 has been. From 1948 to 1973 total national income originating in nonresidential business, shown in the top panel, grew irregularly, with actual declines experienced in 4 years. But by the second year the previous peak had been exceeded in every case. The 1973 peak, in contrast, was not exceeded until 3 years later, and then narrowly. NIPPE, plotted in the middle panel, is a smoother series. Although periods of slower and faster growth alternated, NIPPE increased annually until 1968
and, after a small cyclical dip in 1969 70, again rose strongly until 1973. Thereafter, it fell sharply in both 1974 and 1975 and showed no net increase from 1973 to 1978. At its 1948-73 growth rate, NIPPE would have risen 13 percent in these 5 years.

It is the change in the behavior of the residual series measuring the effects of advances in knowledge and miscellaneous determinants that is most remarkable, however. Because determinants whose effects are directly estimated account for most irregularities in the movement of NIPPE up to 1973, the residual is a rather smooth series with a nearly constant growth rate from 1948 to 1973 and an increase every year. Much of the variation in annual increases that does remain in the
residual appears to be due to the calendar. ${ }^{8}$ Up to 1973 there was no tendency for growth of the residual to slow down. Indeed, its growth rate from 1969 to 1973 was a little above that from 1948 to 1969. Thus the sharp drops in the series in 1974 and 1975 were abrupt departures from past experience. In 1976 the index was still 2.2 percent below 1973 whereas it would have been 4.3 percent above 1973 at its 1948-73 growth rate. The series (and hence the bottom panel of the chart) ends at 1976 but it seems safe to infer from the behavior of NIPPE that, if the residual index increased at all after 1976, the annual gain was far smaller than in the years up to 1973 and that the residual index was further below its 1948-73 trend line in 1978 than in 1976.

# Part 2. The Unexplained Portion of the Decline in Productivity Growth 

THE contribution of advances in knowledge and miscellaneous determinants to growth rates in nonresidential business, as measured by the residual series, fell from 1.4 percent a year in the 194873 period to -0.8 percent a year in the 1973-76 period, with the decline clearly beginning in 1974. The contribution over the whole 1973-78 period was also far below that in 1948-73, it can be inferred from the behavior of NIPPE and output per hour.
That I do not know why the record suddenly turned so bad after 1973 must be obvious, because the effects of all of the determinants of NIPPE that I could measure continuously are excluded from the residual. Perhaps it would be wisest to end with this statement, but I find that to do so leads to insistent questions about what might have been responsible and to requests for comments on specific suggestions. The rest of the article takes up these matters. From the almost limitless list of possible influences on the residual series, I have selected those that have been or may be seriously suggested as important causes of productivity slowdown. Inevitably there is some overlap-
ping among the suggestions examined.
One general point needs stressing. According to my estimates there is no unexplained retardation in the rate of growth of productivity change until 1974, and the drop in the rate that started at that time was abrupt and large. I consider this timing an important clue in any attempt to unravel the mystery surrounding the productivity slowdown. But nearly all the possible reasons advanced for the slowdown would be much more likely to take effect gradually than suddenly. This counts heavily against them. Nevertheless, I have included such suggestions in the following discussion. Most were proposed by observers who, if they had in mind any specific data at all, were trying to explain the slackening in growth that began about 1967 in the Bureau of Labor Statistics series for output per hour.

Of course, "coming events cast their shadows before," and the onset of fundamental changes that were to lead to decline may have been discernible in advance of the actual event. But the unexplained decline itself does not appear until 1974.

## Suggestions Affecting Advances in Knowledge

This section is concerned with four suggested explanations that pertain to advances in knowledge. The two following sections are concerned with 13 suggested explanations relating to miscellaneous output determinants.

## Curtailment of expenditures on research and development

Secretary of Commerce Juanita Kreps, formerly professor of economics at Duke University, has stated that a "Probable source of the slowdown in productivity is the dramatic reduction in expenditures for research and development." ${ }^{9}$ John W. Kendrick, of George Washington University, an expert in productivity analysis, has repeatedly called attention to the decline in research and development (R. \& D.). The conclusions of a 2-day meeting held by the American Association for the Advancement of Science were summarized in The Washington Post as follows: "The United States is losing its competitive edge in technology because American industry is spending less on research and because the Federal Government withdrew much of its support for industrial research at the ends of the Apollo space program and the Vietnam War." ${ }^{10}$
Expenditures for organized R. \& D. in the United States have been much larger in the postwar period than ever before, and within the period, expenditures rose rapidly until the mid-1960's. How one describes their subsequent behavior depends on the series he chooses to emphasize.
If expressed as a percentage of gross national product (GNP), total R. \& D. expenditures rose from 0.95 percent in 1955 to a peak of 2.97 percent in 1964, then slipped gradually to 2.27 percent in 1976 and 1977. The drop was mainly in expenditures financed by the Federal Government, largely for defense and space programs, whose connections with productivity advance is slight. Expenditures financed by other sources (mostly industry but including universities and nonprofit organizations) con-
tinued to climb throughout the 1960's, rising from 0.99 percent of GNP in 1963 and 1964 to 1.15 percent in 1969 and 1970. They then slipped, but only to 1.07 percent, in 1972 and 1973 before recovering to $1.11-1.13$ percent every year from 1974 through 1977. ${ }^{11}$ I have quoted percentages of GNP because this practice is widespread, but its rationale is not clear. Just because the size of the economy is, say, twice as big, does it take twice as much R. \& D. to obtain the same annual productivity gain? Doubtless it would take twice as much R. \& D. if an economy doubled its size by producing twice as many products, each with a unique technology, and no more of any one product. But why should more R. \& D. be needed if growth occurs by expanding the average output of products rather than their number? An invention that cuts 1 percent from the production cost of 5 million automobiles should do as much for 10 million.

Total R. \& D. expenditures themselves, when expressed in constant (1972) dollars, rose rapidly until 1966, when they reached $\$ 28.5$ billion, then less rapidly until 1968, when they peaked at $\$ 29.8$ billion. ${ }^{12}$ Expenditures in all years from 1969 through 1976 were in the range of $\$ 27.7$ billion to $\$ 29.6$ billion, so that in the whole 1966-76 period they were essentially flat. In 1977, constant-dollar expenditures reached a record $\$ 30.2$ billion. Within the total, R. \& D. that was financed by industry increased rapidly until 1969, when it reached $\$ 11.5$ billion, then more slowly to $\$ 13.2$ billion in 1976 and $\$ 13.9$ billion in 1977 . Its annual growth rate was 6.5 percent in 1960-69 and 2.0 percent in 1969-76. ${ }^{13}$ R. \& D. financed by universities (including State and local governments) and nonprofit organizations increased steadily to $\$ 1.1$ billion in 1976 . R. \& D. financed by the Federal Government jumped rapidly to $\$ 17.3$ billion in 1964 , peaked at $\$ 18.2$ billion in 1967 , fell to $\$ 14.4$ billion in 1974 , and recovered to $\$ 14.6$ billion in 1976 and $\$ 15.2$ billion in 1977. ${ }^{14}$

The number of scientists and engineers employed in R. \& D., computed on a full-time equivalent basis, peaked at 558,000 in 1969 , fell 7 percent to

521,000 in 1973, and recovered to 550,000 in 1976 and a record 571,000 in 1977. The pattern in industry was similar: a drop from a peak of 386,000 in 1969 to 353,000 in 1972, then a recovery to 372,000 in 1976 and to 390,000 in 1977. The industry figure includes personnel employed in business who are engaged in federally funded research, including defense and space. ${ }^{15}$

Kendrick constructed a series for the "stock" of knowledge acquired from all components of domestic organized R. \& D. by cumulating past expenditures and applying an obsolescence rate. This series, measured in constant prices, increased at annual rates of 9.6 percent a year from 1948 to 1966 and 5.2 percent from 1966 to 1973 , when it ends. ${ }^{16}$

Like the United States, other advanced countries sharply increased R. \& D. spending, both in absolute terms and as a percentage of GNP, until about 1965. During the middle and late 1960's total R. \& D. spending began to increase less than GNP not only in the United States but also in the United Kingdom, France, and Canada, and after 1970 in West Germany. In Japan, R. \& D. spending continued to increase as a percentage of GNP but more slowly than before. ${ }^{17}$ The absolute amount of foreign R. \& D. spending measured in constant prices increased throughout the period.

To consider the impact of changes in R. \& D. on output per unit of input, it is first necessary to recall that only certain types of advances in knowledge raise output per unit of input as it is actually measured, namely, those that allow the same amount of measured output to be obtained with less input. Advances that do so are those that reduce the unit cost of final products that are already in existence.

Advances leading to the introduction of new products for final sale from the business sector (primarily to households and government) do not have this effect, no matter whether the new products are color television sets, space rockets, atomic-powered aircraft carriers, tastier biscuits, or microwave ovens for household use. After their introduction, total measured product will be the same as if the labor, capital, and land devoted to their production were
used instead to produce previously existing products. When products with new features-for example, refrigerators with automatic ice makers and stoves with self-cleaning ovens-are introduced, they qualify as new products in this formulation. Thus R. \& D. that is directed toward new final products for civilian or military use, even if highly successful in meeting its objectives, does not contribute to the growth of measured output per unit of input except insofar as it may have some incidental offshoots that cut the costs of existing final products. Nearly all federally-financed R. \& D. is in this category and so is the larger part of industry financed R. \& D. Only R. \& D. that is directed either toward new processes, which may be roughly identified with research to reduce a firm's own costs, or toward new intermediate products and capital goods has an objective that, if achieved, raises measured output per unit of input. ${ }^{18}$

Organized R. \& D. in the United States is only one of many points of origin for advances in knowledge that raise output per unit of input, but fortunately it is one (the only one) for which a separate estimate of the contribution to growth has been hazarded. In 1961 I compounded a series of plausible assumptions and guessed that one-sixth of the total contribution of advances in knowledge was the contribution of domestic R. \& D. ${ }^{19}$ A more recent and somewhat more solidly based attempt to estimate this contribution was made by Zvi Griliches of Harvard University. ${ }^{20}$ Griliches estimated that R. \& D. was contributing no more than 0.3 percentage points to the growth rate of private domestic GNP as of 1966 and probably considerably less; his maximum estimate equals less than onefourth of my estimate of the contribution being made by advances in knowledge at that time. ${ }^{21}$

The main elements in these and similar calculations are the value of R. \& D. expenditures for projects that, if successful, can be expected to raise output per unit of input; the social rate of return on such projects; and sometimes the rate of obsolescence on knowledge gained from previous R. \& D. ${ }^{22}$ R. \& D. expenditures are too small to yield

Griliches a contribution above 0.3 percentage points even though he deliberately made a generous estimate of their amount and even though the social rate of return is high.

The large gap between estimates of the contributions of advances in knowledge and of R. \& D. expenditures does not imply that the estimates are inconsistent. As already stressed, organized R. \& D. conducted in the United States is only one source of advances in knowledge. Managerial and organizational knowledge of how to produce at low cost stems from sources that are unrelated to expenditures measured in series for R. \& D. The observation and ingenuity of persons engaged in production and distribution contribute new technological knowledge. So do individual inventors. All types of knowledge originate in all countries, not only the United States.

If R. \& D. contributed no more than 0.3 percentage points to the growth rate in the mid-1960's, retardation of such expenditures could have contributed little, if anything, to the decline of productivity growth even if the percentage of GNP spent on R. \& D. of all types were the relevant series and the period from 1964 peak to 1976 trough were the relevant timespan. The drop in the percentage was about one-fourth, so if the 0.3 percentage point contribution of R. \& D. to the growth rate of output were reduced proportionally, it would decline by less than 0.1 percentage points. Expenditures financed from private sources, measured in constant prices, are a more pertinent series for R. \& D. Since this series did not decline at all, there is no assurance that $R$. \& $D$. spending contributed anything to the decline in productivity growth. Griliches, using a somewhat broader series for R. \& D. spending relevant to productivity growth, suggested that the change in R. \& D. spending from the 1966 rate to the 1970 rate might reduce its contribution by 0.1 percentage points, with the effect perhaps delayed until the mid-1970's. The range from 0.0 to -0.1 percentage points covers the probable change in the contribution.

Kendrick estimated higher contributions from organized R. \& D. than did Griliches or I: The percentage point contributions were 0.85 in 1948-66 and 0.71 in 1966-73. ${ }^{23}$ The high estimates stem from counting in the "stock" all R. \& D. performed in the business sector, including all that is devoted to new and improved products and all that is financed by the Federal Government. As justifications, Kendrick mentions spin-offs and the prevalence of learning curves for all new products, regardless of their buyers, but I do not believe the procedure is tenable. ${ }^{24}$ Even so, Kendrick obtains a reduction in the contribution only slightly in excess of 0.1 percentage points during the period he covered.

Roger E. Brinner of Data Resources, Inc., has, so far as I am aware, the only estimates that show a much larger decline. ${ }^{25}$ His estimate of the contribution of R. \& D. falls by 0.2 percentage points from the 1960-65 period to the 1965-70 period, and then an additional 0.2 percentage points from the 1965-70 period to the 1970-75 period, when he puts the contribution at only 0.05 percentage points. ${ }^{20}$ This unusual set of results apparently stems from the combination of two features of his estimates. First, like Kendrick (whose stock series is Brinner's starting point), Brinner counts government-financed R. \& D., so he has gross additions to knowledge from R. \& D. declining. Second, the amount of old knowledge that he eliminates from the stock, presumably because it is rendered obsolete by new knowledge, is related to the stock of knowledge rather than to the amount of new knowledge, so it rises even when new knowledge falls. This procedure would permit R. \& D. to contribute negatively to growth. ${ }^{27}$

To conclude, as I have, that R. \& D. probably is not responsible for much of the productivity retardation is not to deny that expansion of $R$. \& $D$. is a promising way of promoting future productivity growth. Available studies, though limited in scope, indicate that the social rate of return on $R$. \& D. is high. ${ }^{28}$ This, when combined with the inability of firms financing successful R. \& D. to capture more than a fraction of that return for themselves, provides
justification for policies either to raise that fraction or to increase governmental support.

## Decline in opportunity for major new advances

In the postwar period, advances in knowledge and, in consequence, growth rates of productivity as well as total output have been exceptionally large by past standards. Many have regarded this period as beginning a new era, to be characterized by exponential growth at high rates for an indefinite time. But it is arguable that in the long sweep of history a slackening of the advance in knowledge might reasonably be anticipated quite apart from any reduction in research, and fast postwar growth may appear as a temporary bulge.

The postwar jump in productivity is attributed by some to the crest of a wave of new advances in knowledge made possible by science-based technology, the so-called "second industrial revolution." In their view this wave has passed. This opinion is often based on reasoning such as that of Orio Giarini, who stated that "we are more and more coming to the point where sciencebased technology, at least in certain sectors, has exploited all the major possibilities made available by the scientific advances of the last century," and that we may have to wait decades for the reservoir to be replenished. ${ }^{29}$ Other observers, also envisaging a drop in the contribution of new knowledge, rely on Schumpeter's idea that innovations typically come in waves as an idea spreads and is applied in many fields, and suppose that we have come to the end of such a wave.
F. M. Scherer of Northwestern University, a former Director of the Bureau of Economics of the Federal Trade Commission, suggests, though cautiously, that both explanations may be correct (and their effects exacerbated by the slowdown in R. \& D. expenditures and contracting career opportunities for scientists). To indicate a slackening rate of advance in technological knowledge, he points out that the number of patents issued to domestic corporations peaked in 1971 and declined 20 percent by 1976. Scherer notes that if patents lag 3 years behind inventions, this
would date the invention peak as $1968 .^{30}$
I have no trouble accepting the possibility of declining opportunities for technological advances, but the diversity of the economy should ensure that the resulting retardation of growth would be gradual. The residual shows no sign at all of retarded growth up to 1973. It is not plausible that declining opportunity for new advances could be responsible for much of the sudden drop in the residual after that year.

## Decline of Yankee ingenuity and

 deterioration of American technology"There is today a pervasive perception that the dynamic vitality of the U.S. economy is faltering. This perception appears to be founded on two concerns: first, that America is not as productive as it used to be; and second, that we are somehow not as inventive either." So reads the box summarizing a 1978 Washington Post article, "Something's Happened to Yankee Ingenuity." ${ }^{31}$
Have Americans become less ingenious? To answer this question one would have to isolate possible deterioration in American ingenuity from the possibility, which Giarini regards as a fact, that the remaining problems that would need solving to expand output are more stubborn than those encountered in the recent past. ${ }^{32} \mathrm{He}$ would also have to disentangle changes in the speed with which Yankee ingenuity solves problems of production and distribution from possible lengthening of lags between solution and implementation as a result of new government regulations and other institutional changes. In fact, the main reason for suspecting a decline in Yankee ingenuity seems to be the retardation of productivity growth, a development for which there are many alternative suggestions. Irwin B. Margiloff, industrial executive and engineer, and Delbert Tesar of the University of Florida believe long-run deterioration of American technology is responsible for poor productivity performance, but the deterioration they have in mind set in much too early to explain the recent productivity slowdown. ${ }^{33}$

## Increased lag in the application of knowledge due to the aging of capital

The "best" practice possible with the knowledge available at any given time may be distinguished from the average practice actually in use. Translating this distinction into a classification suitable for analysis of growth, one may distinguish in principle between the contribution made possible by advances in knowledge as such and the contribution (positive or negative) that may be made by a change in the lag of average practice behind the best known.

The residual series under discussion, insofar as it measures the contribution of advances in knowledge, is an estimate of the effects of incorporating new knowledge into the productive process. It therefore includes the effect of changes in the "lag." It is widely suggested that the lag has increased and that this is a reason for the poor performance of productivity.

The most common basis for this belief is that fixed capital formation has declined. This is thought to be germane because it affects the average age of structures and equipment, the carriers of much new technology. Many observers think this was a very important factor. But this is not so. Even the assumptions of an extreme vintage model would yield only 0.1 percentage points as the contribution of the reduction in average age to the growth rate from 1948 to 1973, -0.1 percentage points as the contribution of the increase in average age from 1973 to 1976, and therefore -0.2 percentage points as the contribution of this factor to the decline in the growth rate of the residual. ${ }^{34}$ This calculation assumes that reducing the average age of capital (when its mix is held constant) by 1 year raises output by 1.4 percent, the contribution of advances in knowledge and miscellaneous determinants to the 1948-73 growth rate. Such a model greatly overestimates the effect of a change in average age. One objection is the implausible assumption that all advances in knowledge are embodied in structures and equipment, but a little reflection will reveal a more fundamental objection. During any span of time, different types
of capital goods undergo very different amounts of quality improvement. Other things being equal, the return on replacement investment, and hence the incentive to invest, is highest for types of capital goods that have experienced the most obsolescence resulting from quality improvement in new vintages. Any substantial amount of total gross investment permits investment opportunities created by sizable quality improvements in new capital goods to be grasped. Additional gross investment involves less profitable investment, devoted to the replacement of capital goods of types in which quality change has been small. The gain in the average quality of capital that vintage models imagine to be derived from additional new investment is not realized because the effect on average age automatically is largely offset by a reduction in the average amount of quality improvement incorporated in new capital. ${ }^{35}$
The lag of average practice behind the best known may have lengthened for a different reason: government regulations may delay or prevent remunerative projects using new technology. I discuss this possibility in the context of government regulation.

## Suggested Effects of Government Regulation and Taxation

A variety of explanations for the retardation of output per unit of input would affect miscellaneous determinants. These explanations are often overlapping, and they could be classified and grouped in alternative ways. In this section I consider suggested effects of government regulation and taxation. Government actions that may have reduced output per unit of input are examined here under seven headings. ${ }^{36}$

## Diversion of input to comply with government regulation, except pollution and safety

The most direct way that government regulation affects measured output per unit of input is by requiring business to divert labor, capital, and land from production of measured output to tasks required to comply with regulations.

Under this heading I shall discuss diversions of input other than that imposed by programs for pollution abatement and worker safety and health. The effect of the latter programs, which deducted an estimated 0.3 percentage points from the 1973-76 growth rate, was eliminated before arrival at the residual series. There are, however, other programs that impose similar resource costs, and for which requirements are new or have become more stringent. In the field of consumer protection are regulation of food and drugs by various agencies and regulation by the Consumer Product Safety Commission, created in 1972 to protect the buyers of consumer goods from unnecessary hazards. ${ }^{37}$ Other regulations, such as the national speed limit, are designed to conserve energy or force utilities and manufacturers to substitute one fuel for another; these began only after 1973. Costs in these and other relatively new areas have not been estimated, but they surely increased relative to national income from 1973 to 1976 and contributed to the decline in the residual. However, Robert W. Crandall, Senior Fellow of The Brookings Institution, states that of the agencies entrusted with social regulation, the two having the largest impact on business costs are the Occupational Safety and Health Administration (OSHA) and the Environmental Protection Agency (EPA), both covered by my estimates for pollution abatement and worker safety and health. ${ }^{38}$ This statement tends to be supported by a study of the 1977 incremental costs imposed on 48 large companies by six programs. Incremental costs to these companies imposed by requirements of the Equal Employment Opportunity Commission (EEOC), the Department of Energy, the Employee Retirement Income Security Act, and consumer protection activities of the Federal Trade Commission, together, were 19 percent as large as the incremental costs imposed by EPA and OSHA. ${ }^{39}$

I should be surprised if the increase in the total resource costs, except paperwork costs, of all other regulatory programs together affected the change in output per unit of input as much from 1973 to 1976 as that attributable to the
two programs for which I made estimates. But it is also likely that these costs have been rising sharply.

## Government-imposed paperwork

Filing reports, making and preserving records, and compiling data in order to meet government requirements also absorb resources that could otherwise be used to produce measured output. Most of these costs are associated with tax collection or with regulatory ac-tivities-for example, railroad rate or pension fund regulation-that do not otherwise require diversion of an appreciable amount of input from the production of measured output.

The Commission on Federal Paperwork estimated that paperwork necessary to meet the requirements of the Federal Government cost American business $\$ 25$ billion to $\$ 32$ billion in 1976. ${ }^{40}$ This is 2.4 to 3.1 percent of 1976 nonresidential business national income. The requirements of State and local governments may have raised the percentage by one-fourth to one-half, bringing it into the $3.0-4.6$ percent range. ${ }^{41}$
Estimates of the total hours required to meet Federal reporting requirements, assembled from agency reports by the Office of Management and Budget (OMB), suggest that business reports to the Federal Government required perhaps 530 million hours a year as of January 1977.22 This is only 0.2 percent of total hours worked in nonresidential business in 1976 and thus suggests a much smaller paperwork burden than do the dollar estimates; it seems, in fact, incredibly small. ${ }^{43}$
Whether the higher or lower percentages for the level of the paperwork burden are correct, the following considerations show that the burden cannot have increased enough to depress productivity significantly from 1973 to 1976 if the OMB's allocation of the man-hour estimates among programs is anywhere near correct. OMB analyses indicate that major changes in the burden are the result of changes in programs. ${ }^{44}$ Tax forms account for perhaps four-fifths of all the hours, and there were no major changes in the tax area; all of the principal tax forms go back to at least $1963 .{ }^{45}$

The number of public use reports subject to OMB review, which excludes tax forms, peaked in 1944, 1952, and 1973 because of economic controls (wage and price controls in all three periods and, in the first two, production and resource allocation regulations as well). Statistical series for the number of such reports were disrupted after 1973 as responsibility for reviewing reports for regulatory commissions and certain other agencies was transferred from the OMB to the General Accounting Office. But it is known that elimination of wage and price controls had eliminated much reporting by 1976. Although new types of Government regulation created new paperwork requirements, the OMB estimates that the total hours outside the tax area declined from 1973 to 1976.

Thus the evidence indicates that paperwork can be eliminated as a significant source of productivity decline from 1973 to 1976 , although it may have been a factor-but not a major one-if one goes back to 1966. The general impression of the burden of paperwork may be exaggerated because, in Herbert Kaufman's phrase, red tape is universally an "object of loathing." ${ }^{47}$

## Regulation and taxation: diversion of executive attention

The profitability of a business is now greatly affected by the way it responds to rapid changes in government action, not only with respect to regulation but also to provisions in the tax laws that discriminate among different types of income and different business costs. Under these conditions it is not surprising that top management and other business people of great talent devote more and more of their time to the firm's interaction with government and correspondingly less time to its interaction with competitors, customers, and suppliers and to its internal operation. This can hardly fail to impair efficiency and productivity in the ordinary sense of these words.

A burgeoning of regulation during the past decade has affected practically all the domestic and foreign activities of businesses in every industry, so much so that Senator Lloyd Bentsen, Chairman of the Joint Economic Committee's

Subcommittee on Economic Growth and Stabilization, calls Federal regulation "America's number one growth industry." ${ }^{48}$ Failure to learn of and conform to regulations can have serious legal consequences, including criminal penalties. ${ }^{49}$ Failure to find the cheapest way to conform can be expensive. Failure to learn of proposals for new laws or regulations and to participate in hearings and use other channels to help shape their final form can bring permanently higher costs or loss of markets. So can failure to foresee changes in laws and regulations and to take timely action in advance to minimize losses or maximize gains from the change. ${ }^{50}$

Not only laws and regulations actually proposed or made effective are pertinent; one must guess at what may be proposed in the future. In the words of Irwin L. Kellner, vice president and economist of Manufacturers Hanover Trust, not only have laws, rules, regulations, and regulatory agencies leaped upward in number, but they "have become increasingly unpredictable of late. Unlike economic, technological, or other uncertainties indigenous to the private free enterprise system, political uncertainties tend to be sudden, swift, and unprecedented." ${ }^{51}$ Now that mandatory price and wage controls have been introduced once in peacetime, business must (and does) consider the possibility that such controls will be repeated and position itself appropriately. The spring and summer 1978 quarterly surveys of businessmen conducted by the U.S. Chamber of Commerce showed a majority anticipated mandatory wage and price controls within 2 years. In the same year, regulation displaced taxation as the greatest concern of respondents to the chamber's surveys.

Glen McLaughlin, vice president for finance of Four Phase Systems, Inc., of Cupertino, California, says:
"Corporations have been burdened with regulatory excess to the point of stifling normal improvement in efficiencies. Business leaders can and will continue to assume additional taxes and regulations; however, as each new tax and each new regulation is imposed, another layer of incentive to perform is
removed and otherwise creative efforts are diverted to nonproductive, but lucrative, jobs of avoiding taxes and doing battle with bureaucrats. This is a tremendous waste of national resources; however, it is occurring at an accelerating rate." ${ }^{52}$

George C. Eads of the Rand Corporation suggests that the change in emphasis among the activities that are required for a business to prosper must also affect the type of person who will emerge to manage firms. Presumably more emphasis will be placed on knowledge of the law, the legislative process, and public relations and less on production, sales, and internal management. ${ }^{53}$

Concern about government regulation is not confined to top management. Murray L. Weidenbaum of Washington University points out that:
"Virtually every major department of the typical industrial corporation . . . has one or more counterparts in a federal agency that controls or strongly influences its internal decision making: OSHA for 'production'; the Consumer Product Safety Commission for 'marketing'; several agencies concerned with safety and efficiency rather than sales promotion for 'advertising'; EEOC for 'personnel'; IRS, SEC (Securities and Exchange Commission), and the credit agencies for 'finance'; EPA for 'research and development'; and so on." ${ }^{54}$

## Government regulation: delay of new projects

Government regulatory requirements for applications, permits, and reports give rise to delays between first consideration and completion of projects, and the spread of regulation has undoubtedly lengthened delays substantially in recent years. ${ }^{55}$ The difficulty of coordinating several permits from different agencies may result in long delays or even abandonment of projects. ${ }^{56}$ The timespan between administrative receipt of an application and a decision is often long, and delays are greatly extended by judicial appeals. Delays resulting from government regulation not only slow the introduction of new ideas and new technology, but also reduce the flexibility of firms in dealing
with recurrent changes in production and marketing conditions.

Increased delay stemming from increased regulation unquestionably contributed to the recent retardation of productivity growth. No estimate is available of the amount by which it did so.

## Regulation and taxation: misallocation of resources ${ }^{57}$

Efficiency is greatest when individuals and jobs are properly matched (the round pegs are in the round holes) and when total input is allocated among uses in such a way as to maximize output. Government regulations and various provisions of the tax code affect resource allocation, and hence output, in many ways.

Because of privacy legislation, which denies confidentiality to appraisals of students, government employees, and other groups, prospective employers must find references of less value. Civil rights legislation has added new criteria for hiring, promotion, and release of workers that may affect resource allocation positively in the long run, yet in the short run be adverse to the selection of the best person for each job. It also adds to costs of personnel management. ${ }^{58}$

At the macro level the tax code is packed with provisions that discriminate among types of expenditures and kinds of activity. For example, the investment tax credit has discriminated against inventories and structures in favor of producers' durables, and among producers' durables against those with the longest and shortest service lives. Neither inventories nor structures were eligible for any investment tax credit in the period under review. The credit on producers' durables was proportional to gross investment rather than to capital stock, a formula that discriminates against longer lived assets, but also contained a provision for graduated rates that more than offset that difference among durables with a service life of less than 7 years. The President's Council of Economic Advisers calculated that if the rate of return was 10.0 percent before allowance for the investment tax credit, the credit raised the rate of return to 11.57 percent if the asset had a 4 -year service life, to 13.30 percent if it
had a 7 -year life, and to 11.31 percent if it had a 30 -year life. ${ }^{59}$ The 1978 tax amendments made structures eligible for the credit but their long service lives assure that the benefit will be small relative to producers' durables.

New government regulations, like old ones, contain provisions to protect regional, industrial, or other special interests. Other provisions serve only to appeal to uninformed prejudices; an example is the prohibition of the exportation of surplus Alaskan oil from the west coast to Japan and the offsetting importation of oil on the Atlantic and gulf coasts.
Perhaps the aspect of regulation most adverse to efficient resource allocation is increased uncertainty. I do not refer now to the effect this uncertainty is sometimes said to have on the amount of investment; rather, I am concerned here with its effect on composition. The enormous change in the scope of regulation is sometimes said to have placed nearly all business in the category of regulated industries. When an investment decision must be made, the way that regulations will be applied in the specific instance and the length of time that will be required to secure all necessary regulatory decisions so that a project may proceed are important, but the difficulties of deciding the characteristics of a project or of determining the future benefits from it are accentuated by the prospect that regulatory conditions may change once a facility is in use, altering the optimal combination of inputs and conceivably even banning the sale of products. It is a reasonable inference that the allocation of the capital stock among types and uses must depart further from the optimal allocation at any given time than it would if regulations were less pervasive, changing, and uncertain in application. The wedge introduced by regulation between costs and benefits that are anticipated and those that are realized probably is increasingly widened as the planned life of investment lengthens, so regulation probably moves the distribution of investment toward shorter lived assets, as is frequently asserted. But this is only a detail within the general picture.

Effects of high tax rates on incentives and efficiency
Beryl W. Sprinkel, economist and executive vice president of the Harris Trust and Savings Bank, believes that:
"The reason for the poor performance of our economy [that is, significantly deteriorating productivity trends in the past dozen years, accompanied by accelerating inflation] has been the growing burden of government. The tax burden at all levels of government in 1966 was 33 percent of national income. This past fiscal year the tax burden rose to a record 39.2 percent of national income. Although voters perceive taxes paid as the cost of government, the real economic cost is represented by the share of national income devoted to government outlays. This figure rose from 34 percent of national income in fiscal 1966 to 41 percent last year." ${ }^{60}$
One way a large government share might reduce productivity is by contributing to inflation, which (as explained in a later section) may impair efficiency. It was inflation that Colin Clark, the Australian author of The Conditions of Economic Progress, forecast as the disastrous result if government expenditures exceeded 25 percent of national income. ${ }^{61}$ Subsequently others have forecast various dire consequences, including impaired growth of both productivity and total output, at some higher percentage. The assertion that high taxes diminish incentives to work and to save is commonplace.

Herbert Stein, professor of economics at the University of Virginia and a former chairman of the President's Council of Economic Advisers, examined this view, which he described as follows:
"The argument that increased government spending, as a share of GNP, slows down the rate of growth of real output runs along familiar lines. The higher taxes needed to finance the higher spending would weaken incentives to work and to invest, and would absorb funds that otherwise would have been saved and invested. If the government borrows to finance its expenditures, that will crowd out private investment. A more recent version of this view is that the absorption of productive resources by the government cuts
the supply of resources available to produce investment goods and marketable consumption goods, which will reduce private investment especially, since workers will resist reducing their consumption of marketable goods. Another aspect to be considered is that increased government spending absorbs workers into public employment, where productivity is low and growing slowly if at all, and that this restrains the growth of total output." ${ }^{62}$

If the consequences of large budgets asserted in this argument were confined to a reduction of the labor and capital used in nonresidential business, they would not reduce output per unit of imput in the sector. ${ }^{63}$ They would do so only if the effect on labor took the form of people working less hard while at work or refusing promotions.
But Stein finds little support in the American experience for any of the processes he described. In particular, "no stagnation of growth was evident during the period of high and rising government expenditures." Nor is any effect on the private saving rate or much, if any, on employment to be observed. Stein finds that the evidence suggests that the effects of government spending and taxes on economic growth during the period from 1956 to 1973 were "at least uncertain and probably small." ${ }^{64}$

The period after 1973 was one of poor growth and productivity performance but not one in which the government share shot up abruptly. Federal, State, and local government expenditures, which rose from 24.8 percent of GNP in 1956 to 31.0 percent in 1973, went to 33.5 percent in 1976 and 32.5 percent in 1978. The increase from 1973 to 1976 was partly due to increased unemployment. Government receipts were 26.1 percent of GNP in 1956, 31.0 percent in $1973,31.6$ percent in 1976, and 32.4 percent in $1978 .{ }^{65}$

I agree with Stein that the general size of government budgets has not had a substantial adverse effect on growth and productivity. This does not necessarily mean, of course, that there would be no such effect from a further increase, such as has recently been experier in several European countries. In Netherlands, the three Scandinavian
countries, and the United Kingdom, general government expenditure reached 44 to 51 percent of gross domestic product in 1975, compared with 34 percent in the United States. ${ }^{60}$

## Capital gains provisions of the Revenue Act of 1969

William F. Ballhaus, president of Beckman Instruments, Inc., ascribes the recent slowdown in growth and productivity to the provisions of the Revenue Act of 1969 that affected capital gains. Previously, only half of long-term capital gains (then gains on assests held 6 months or more) were subject to the Federal individual income tax, and the rate on this half was limited to 50 percent, so the top effective marginal rate was 25 percent. ${ }^{67}$ The Revenue Act of 1969 , effective January 1, 1970, deleted the 50 percent rate ceiling; this raised the effective rate for high-income individuals from 25 percent to 35 percent. For a small number whose income was largely from sources given preferential tax treatment, the effective marginal rate could be higher, as much as 49.1 percent, as the result of a new minimum tax provision of the law, or even 52.3 percent for a few individuals with large foreign tax credits. In addition, the period for which assets had to be held for gains on them to qualify as long-term rather than short-term gains (which are taxed like ordinary income) was to be increased, but this provision became effective only in $1977 .{ }^{68}$

Ballhaus sees the increased taxation of capital gains as the cause of reduced investment. ${ }^{69} \mathrm{He}$ also sees it as the cause of reduced spending for research and development. ${ }^{70}$ Even if these effects were sizable, they probably contributed little to the slowdown in the residual. ${ }^{71}$ Less investment reduces capital input, not the residual, although it does affect output per hour. Less R. \& D. would tend to reduce the residual, but R. \& D. has already been rejected as a probable cause of very much of the productivity slowdown.

But Ballhaus has a third effect: Taxation of capital gains biases the distribution of investment and R. \& D. away

- the more risky undertakings. This
nother cause of misallocation
of resources that would reduce the residual. It seems inescapable that capital gains taxation has such a tendency, and therefore that higher capital gains taxation increases the tendency. This statement does not rely on an assumption that investors are averse to risks. A $\$ 1$ million investment certain to repay $\$ 1.1$ million has the same expected return as a $\$ 1$ million investment that has nine chances of becoming a total loss and one of repaying $\$ 11$ million, and the two investments are equally advantageous to society. But if the government shares in gains but not in losses, the safer investment promises the higher return to the investor. Ballhaus assigns a particularly strategic role to individual investors in small companies, and states that equity investment in small companies declined after 1969 and almost vanished in 1973-75.

The argument that high capital gains taxation impedes growth became central in 1978 to the case for Congressman William A. Steiger's proposal to restore the situation that existed before the Revenue Act of 1969. The tax bill actually passed in 1978 was not much less favorable than his proposal for any taxpayer and even more favorable for most. Sixty percent of long-term gains, as against the previous 50 percent, was exempted from income tax and this, together with changes in the minimum tax and the enactment of a new "alternative minimum tax," reduced the highest effective marginal tax rate on capital gains to 28 percent. If the 1969 change in capital gains taxation was an obstacle to growth, that obstacle has been removed.

However, the increase in the tax yield from capital gains that resulted from the 1969 law was less than $\$ 1$ billion at 1978 income levels, according to Treasury Department estimates. The small size of the extra tax burden suggests that the misallocation resulting from it, though doubtless present, was not large.

## Other Suggestions Affecting Miscellaneous Determinants

In this part of the article I consider six additional causes that have been suggested for retardation of the growth
rate of productivity and that would affect my residual series. Like suggestions considered in the preceding section, their effects, if any, would be on miscellaneous determinants of output, including aspects of labor input and resource allocation for which specific estimates were not prepared.

## 'cPeople don't want to work any more"

The press recently quoted me as stating-as I have here-that productivity had declined, in part for reasons that were mysterious. The result was long-distance calls informing me, usually with the patronizing air used in speaking to children and the simpleminded, that the trouble is obvious: "People don't want to work any more." Sometimes the comment was more pointed: "Young people don't work like we did at their age." This is without doubt the number one popular explanation of low productivity. It is also shared by some economists.

Thus Arthur F. Burns, then Chairman of the Board of Governors of the Federal Reserve System and previously president of the National Bureau of Economic Research and Chairman of the President's Council of Economic Advisers, devoted most of his 1977 commencement address at the University of South Carolina to this theme. ${ }^{72}$ "Careful study [of labor force composition and capital per worker] still leaves a substantial part of the recent productivity slowing unexplained," he stated. "Other adverse influences apparently have been at work as well. My own judgment is that we have been undergoing a change in our societal values and attitudes that has contributed significantly to poorer job performance in recent years. I advance that as a hypothesis only, not as an established fact. It is a hypothesis, however, for which there is regrettably a considerable body of supportive evidence." ${ }^{73}$

The attitudes and behavior that trouble Burns and so many others are highly visible. And the difficulty of finding reliable workers for jobs that are particularly hot, dirty, noisome, arduous, or regarded as menial can scarcely be denied, though this may be more the result of improved alterna-
tives than of changes in workers' preferences.

Yet I am skeptical that a sudden drop in willingness to work is responsible for the recent retardation of productivity, whether that is dated after 1966 or after 1973. My skepticism is largely attributable to having heard similar generalizations all my life and having read them in the works of observers who wrote long before my birth. It was well before 1967 that I wrote, "Like the supposed decline in the spirit of enterprise, there seems always to be a popular belief that people are less willing to 'put in a hard day's work' than they used to be, but this is scarcely evidence." ${ }^{74}$

These generalizations, moreover, are also common in other countries, including those with excellent records for raising productivity. And they are not new there either. Thus the Tokyo Mainichi Daily News editorialized on April 7, 1976:
"Opinions have been expressed at offices and factories that today's young people are not eager to work. The view is not anything new. Every generation seems to say the same thing about its youths. Still, young people must seriously ponder the allegation. . . . We . . . exhort the newly employed young people to tackle their work with due seriousness.
"A government survey shows that two thirds of today's youth want to live a carefree life to their personal taste outside concern about work. If they want to take a job, however, they are required to care more seriously about work. A switch is needed in their life style concept."
Testimony about a similar observation in Germany comes from Walter W. Heller, another former Chairman of the President's Council of Economic Advisers and an expert on the puritan ethic, who dissents from the Burns view about "this supposedly weakening work ethic." Heller noted:
"Ludwig Erhard used to tell me that 'the world-famous German diligence has disappeared.' He told me that in the fifties, and he told me that in the sixties, and now I am hearing it in the seventies." Burns' very interesting response to Heller was: "It has been true each time." ${ }^{75}$

It is indeed possible, as those quoted have suggested, that always and everywhere work effort has declined and has curtailed productivity growth. If so, my residual persistently understates the contribution of advances in knowledge. But even if this pattern were an accurate description, it would not explain a downturn in recent years in my residual. It is also possible, as Solomon Fabricant has suggested, that over long periods work effort has fluctuated and that the impressions reported all refer to the declining phases of these cycles. ${ }^{76}$

Is there any reason at all for a recent (post-1966 or post-1973) sudden sharp decline in work effort from its past trend, whatever that trend may be? One possibility, perhaps slight, was suggested in Accounting for Growth. "Programs to hire the 'hard core' unemployed that do not require them to meet as stringent performance standards as those applied to the ordinary work force pose a possible danger: acceptance of lower standards for a special group in an establishment may reduce performance standards for the rest of the work force in that establishment." ${ }^{77}$ Hiring to meet objectives of legislation to promote equal employment opportunities has a similar potential. "On the other hand," as I wrote, "such programs may help to remove irrelevant hiring tests or other forms of disguised discrimination." ${ }^{78}$

My series for average hours, which enters into the calculation of total input, measures time spent at the work place. The Survey Research Center at the University of Michigan reports that time records kept by a small sample of married men showed the ratio of time actually worked to time at the work place to have been 2 percent lower in 1974-76 than in 1965-66. ${ }^{79}$ Whether there was a change in trend, and if so, when it occurred, cannot be ascertained from these data. The concept of time actually worked is obviously a difficult one for many categories of workers.

I have no desire to minimize the importance of work effort. In Why Growth Rates Differ I suggested that higher intensity of work in the United States than in at least several of the European countries may well help to account for the higher level of productivity in the

United States. I also stated that an "inability to answer the simple questionhow hard do people work?-and to compare different places and dates, is probably the most serious gap in my measure of labor input." ${ }^{80} \mathrm{It}$ is quite possible that a decline in work effort contributed something to the retardation of productivity, although this has not been demonstrated. But it is unlikely to have been a major cause of the suddenly retarded growth of the residual after $1973 .{ }^{.81}$

## Impairment of efficiency by inflation

Inflation is widely thought to impair growth of output per hour or per worker by reducing saving and investment. ${ }^{82}$ In my classification this effect would be captured by the contribution of capital and would not reduce output per unit of input or the residual series. A consequence of inflation that would do so is rendering rational calculations by businessmen more expensive and less accurate. When prices are changing rapidly, information about prices charged in different markets and outlets is quickly outdated. ${ }^{83}$ So is knowledge about wage rates and interest rates. The problem is intensified if, as stated by the Bank for International Settlements, "a high average rate of inflation almost certainly entails an increased variance of individual price changes." ${ }^{84}$ As Arthur M. Okun, Senior Fellow of the Brookings Institution and a former Chairman of the President's Council of Economic Advisers, says, inflation "disturbs a valuable set of institutions that economize on information, prediction, and transaction costs through continuing employer-worker and buyer-seller relationships." ${ }^{85}$ Many others have pointed out that inflation erratically affects the tax burden, especially that of firms, because the tax system is based on nominal incomes and book profits. ${ }^{86}$

In his Nobel lecture, Milton Friedman of the University of Chicago discussed limitations of indexing as a method of minimizing the impact of inflation on efficiency. Inflation that is high on the average tands to be highly variable in its rate, and "increased variability shortens the optimum length of unindexed commitments [which
would itself increase transaction costs] and renders indexing more advantageous. But it takes time for actual practice to adjust. In the meantime, prior arrangements introduce rigidities that reduce the effectiveness of markets. An additional element of uncertainty is, as it were, added to every market arrangement. In addition, indexing is, even at best, an imperfect substitute for stability of the inflation rate. Price indexes are imperfect; they are available only with a lag and generally are applied to contract terms only with a further lag.
"These developments clearly lower economic efficiency." ${ }^{87}$
Friedman also effectively states the general inefficiency argument." "A second related effect of increased volatility of inflation is to render market prices a less efficient system for coordinating economic activity. A fundamental function of a price system . . . is to transmit compactly, efficiently, and at low cost the information that economic agents need in order to decide what to produce and how to produce it, or how to employ owned resources. The relevant information is about relative prices-of one product relative to another, of the services of one factor of production relative to another, of products relative to factor services, of prices now relative to prices in the future. But the information in practice is transmitted in the form of absolute prices-prices in dollars or pounds or kronor. If the price level is on the average stable or changing at a steady rate, it is relatively easy to extract the signal about relative prices from the observed absolute prices. The more volatile the rate of general inflation, the harder it becomes to extract the signal about relative prices from the absolute prices: the broadcast about relative prices is, as it were, being jammed by the noise coming from the inflation broadcast. ... At the extreme, the system of absolute prices becomes nearly useless, and economic agents resort either to an alternative currency or to barter, with disastrous effects on productivity. . . .
"These effects of increased volatility of inflation would occur even if prices were legally free to adjust-if, in that sense, the inflation were open. In prac-
tice, the distorting effects of uncertainty, rigidity of long-term contracts, and the contamination of price signals will almost certainly be reinforced by legal restrictions on price change. In the modern world, governments are themselves producers of services sold on the market: from postal services to a wide range of other items. Other prices are regulated by government and require government approval for change: from air fares to taxicab fares to charges for electricity. In these cases, governments cannot avoid being involved in the price-fixing process. In addition, the social and political forces unleashed by volatile inflation rates will lead governments to try to repress inflation in still other areas: by explicit price and wage control, or by pressuring private businesses or unions 'voluntarily' to exercise 'restraint,' or by speculating in foreign exchange in order to alter the exchange rate." ${ }^{88}$

That inflation impairs productivity seems certain. But I have no idea how much it may have done so from 1973 to 1976.

## Lessening of competitive pressure and changes in the quality of management

According to my calculations, output per unit of input in the United States surpassed that in Western Europe (in 1960) and Japan (in 1970) by a much wider margin than is explained by determinants whose effects I could calculate directly. ${ }^{89}$ In discussing the differential with Europe, I listed less intense competitive pressures in Europe among probable contributors to the differential, noting that "less competition means that inefficient firms and inefficient management are under less pressure to minimize costs and less likely to be displaced by those who can do better." I also wrote: "In the field of 'managerial knowledge' it is probably futile to distinguish between what management knows and what management does with the knowledge it has; but somewhere in this area, I suspect, lies an important part of the explanation for the productivity differential." ${ }^{30}$ Competitive pressure clearly affects management quality but is not the only influence on it. I have suggested
that increased competition and improved management probably contributed to the increase over time in efficiency in France. Eleanor M. Hadley of George Washington University and the General Accounting Office concluded that increased competition has done so in Japan. ${ }^{91}$

When I examined American economic growth in 1961, I quoted Edward S. Mason and Theodore J. Kreps to the effect that either there had not been a change in monopoly or the size of the competitive area in America or it was impossible to know whether there had been any change. ${ }^{92}$ This seems still to be the case.
The only broad quantitative measures available refer to concentration in manufacturing industries. The fourfirm concentration ratio for an industry is the percentage of the industry's shipments made by the four firms with the largest value of shipments. A summary measure can be obtained by computing weighted average concentration ratios for all manufacturing industry, letting each individual industry's four-firm ratio be weighted by the value added originating in that industry. F. M. Scherer has provided such ratios for several years: ${ }^{93}$

| 1947 | 35.3 |
| :---: | :---: |
| 1954 | 36.9 |
| 1958 | 37.0 |
| 1963 | 38. |
| 1972 | 39 |

Although there is some increase in concentration, it is small from 1963 to 1972. The increase up to 1963 seems to result mainly from changes in industry composition and weights; with constant weights and constant industry definj-tions-but unavoidably, much less complete coverage-the percentages are those shown below:

| 1947 | 38.0 |
| :---: | :---: |
| 1954 | 38.1 |
| 1958 |  |
| 1963. | 37.9 |
| 1972 | 38. |

I am aware, of course, that some observers believe the breadth and strength of competition has declined. Sometimes this belief is related to the argument of a previous section, which
described how the need to interact with the government has diverted executive attention from competition and other conventional concerns. Other alleged effects of regulation (including financial regulation) are the heightening of barriers against the entry of new firms and the elimination of small firms that are unable to afford compliance costs (although the latter seems to be more a forecast of things to come than a description of events up to 1976). Conglomerate mergers, which peaked in number and value in 1966-68, are sometimes suspected of having lessened competition, but Peter O. Steiner of the University of Michigan, who cites Jesse W. Markham of Harvard University and the Bureau of Economics of the Federal Trade Commission in addition to his own analysis, found no major effect of this type. ${ }^{94}$ On the other side, it is pointed out that foreign competition has become much more intense. Also, recurrent and persistent underutilization of resources since 1969 has cut into profits and made for a highly competitive situation.

Burton H. Klein of the California Institute of Technology places great emphasis on competition-or to use his term, "rivalry," which he particularly associates with battles for market shares-as the engine driving firms to improve technique and especially to lower costs. ${ }^{95} \mathrm{He}$ regards the early postwar "golden age" as "primarily the result of a highly competitive economy generating a wide diversity of ideas." As Klein sees it, the situation has changed, evidently, since about 1965. "The dynamism of the American economy is highly dependent upon new firms. . . ." Klein believes the entry of new firms has become rare, primarily because of the unavailability of risk capital for new firms. "Openness" of firms, which in Klein's terminology is the opposite of a closed hierarchical system that is resistant to new blood and radical new ideas, has diminished. "A decline in openness," he reports, "has caused large firms to become more structured and, as such, less able to deal with risk. Moreover, the change in internal incentives results in the selection of managers with quite different personality characteristics. And there
is a good deal of evidence that imaginative scientists and engineers are being replaced with business school graduates and lawyers, that is, by people who perform the same function in modern societies as did genetic inbreeding in feudalistic societies." ${ }^{96}$ It is evident that Klein blames loss of rivalry for alleged managerial changes that others ascribe to government regulation.

Managerial behavior is, of course, subject to many influences. For example, Alfred Rappaport of Northwestern University believes that executive compensation systems often instill a drive to produce short-term results, influencing management to forego investment in capital equipment and R. \& D. and to take other actions, such as corporate takeovers, that sacrifice longer term earnings to secure short-term accounting profits of less value to the firm. ${ }^{97}$

## Rise in energy prices

The sharp drop in the growth of the residual series coincided with the sudden increase in OPEC oil prices at the end of 1973 and in early 1974. Explanations that ascribe the productivity drop to the oil price increase are therefore exceptional in that they account for the timing of the drop. ${ }^{98}$ One study described later in this section, that by Rasche and Tatom, even estimated the effect to be of a size about equal to the amount by which growth of the residual deteriorated. To be able to accept this estimate would be doubly satisfying because it would not only solve the productivity mystery but also would be somewhat reassuring for the future. For even if a one-time fuel price increase permanently lowers the level of productivity, it should not reduce the subsequent growth rate once the transition is completed. Unfortunately, the Rasche-Tatom estimate appears to be many times too big, for reasons explained below, and I do not think that much of the productivity slowdown can be ascribed to energy prices.

It is necessary to distinguish three effects of the oil price increase. First, the increase in the price of imported oil was the main component of a deterioration in the terms of trade that reduced the Nation's command over goods and
services by about 1 percent, but this did not directly change national income (or other output measures, such as GNP) or productivity. ${ }^{99}$ Hence the "terms of trade" effect can be ignored here. Second, the Government did intervene, with controls over fuel consumption and choice of fuels, to try to reduce present and future imports. These were among the many new controls discussed earlier. Third, the high price of energy resulting from the higher price of imported oil probably caused nonresidential business to use less energy per unit of labor, capital, and land. ${ }^{100}$ The questions that must be explored here are, How much? And what was the effect on output per unit of input? This section describes some studies.
The usual way to approach the subject is to treat energy as if it were a factor input. Energy gets about 5 percent of the total input weight in the business sector, according to Roger Brinner. ${ }^{101}$ Data from the Nuclear Energy Policy Study Group, when combined with estimates by Sam H. Schurr and Joel Darmstadter of Resources for the Future, yield about the same result, 4.6 percent. The calculation is as follows. The Study Group put the cost of primary energy in 1975 at $\$ 70$ billion. ${ }^{102}$ Schurr and Darmstadter state that "no more than 60 percent of yearly energy use goes to the (nonresidential) business sector." ${ }^{103}$ Hence the value of primary energy used by nonresidential business can be put at $\$ 42$ billion in 1975 , which was 4.6 percent of a $\$ 916$ billion nonresidential business national income. ${ }^{104}$ This percentage is based on energy prices after the 1973-74 oil price increase; before the increase it was smaller.

Given the weight of energy, the effect on output per unit of input of any given percentage decline in energy use by nonresidential business depends on the elasticity of substitution between energy, on the one hand, and labor and capital, on the other. If the elasticity of substitution is unity and the weight of energy is 5 percent, a 1-percent reduction in energy consumption with no change in labor and capital would reduce output by 0.05 percent and out-
put per unit of input by the same percentage.

To be sure, this approach has difficulties. The amount by which the price rise may have reduced fuel consumption in nonresidential business is hard to estimate. One reason is that it is not easy to say what would have happened to total energy consumption after 1973 in the absence of a price change, because earlier experience was not uniform. ${ }^{105}$ The ratio of total energy consumption to GNP has declined in the long run-say, since 1920-but not steadily; there was little net change from about 1953-54 to 1973. Short-run fluctuations in the ratio have been sizable, reflecting in part effects of the business cycle and war. Worse, a suitable time series for actual energy consumption by nonresidential business has not been compiled for either the historical or recent period. ${ }^{108}$ Much of the energy supply is used to heat, air condition, and illuminate dwellings and government buildings; for cooking and household appliances; and to operate consumer and government motor vehicles, planes and ships. The re-mainder-that is, nonresidential business use-may not have moved as the total did. Partly because of these difficulties, only rough impressions of the elasticity of substitution are available.

Moreover, energy is not really a factor input but is itself the product of labor, capital, and land (natural resources). At the point where it reaches the user. most of its value consists of the earnings of the labor and capital required to transform a natural resource into the form needed by energy users and move it to where it is needed. Additional energy can always be provided by adding labor and capital, although it may require the use of poorer natural resources requiring more labor and capital.

This suggests another approach to the question. Suppose 20 percent of energy were imported and higher import prices caused imports to be cut by one-fourth ( 5 percent of consumption). The loss could be made good without changing consumption by raising domestic energy production from 80 percent to 85 percent of consumption. Suppose the cost in labor and capital
per unit of energy were as much as twice as high for the additional energy as for existing domestic production. If 80 units of labor and capital were required to produce 80 percent of consumption, 90 units would be required to produce 85 percent of the same consumption. The labor and capital requirement for domestic energy production per unit of energy would be raised to 105.9 percent $(90 \div 85)$ of the original requirement. This would leave business with as much energy as ever. If domestically produced energy were initially 4 percent of nonresidential business output and input, output per unit of labor and capital in nonresidential business would be reduced by 4 percent of 5.9 percent, or 0.24 percent. This figure could be reduced by some substitution of labor and capital for energy. These import substitution numbers are only illustrative, but they suggest the dimensions of the effect.
I turn now to actual estimates that have been made of the effect of the energy price increase on the course of productivity after 1973. George L. Perry, a Senior Fellow of The Brookings Institution, has made what I regard as the most reasonable calculation. ${ }^{107}$ Perry prepared a time series for nonresidentia] business use of energy, measured in BTUs, that begins in 1949. It covered about three-fifths of the total; the main omissions were commercial uses of petroleum for heating and transportation. For the 1949-73 period (as well as for subperiods) he related this series for energy use to gross business product, the ratio of actual to potential gross business product, and the trend in the ratio of energy use to output (which is downward by 1.3 percent to 1.6 percent a year). He then used three alternative equations based on these data to predict the ratio of energy use to gross business product in 1976. They predicted declines from 1973 to 1976 of $7.3,7.0$, and 5.3 percent, respectively. The actual decline was 10.2 percent. The difference of 2.9 to 4.9 percent between actual and predicted reductions is an estimate of the reduction one can ascribe to higher energy prices or other unspecified factors, including Government controls. Perry considers this a maximum estimate because the equations assume a
constant downtrend through 1973 in energy per unit of gross business product, whereas the decline was actually accelerating. (If the estimated 1973-76 decline in the absence of the price rise is understated for this reason, the effect of the price rise on energy use is overestimated.) Perry next estimates that the value of the energy saved by the 2.9 - to 4.9 -percent reduction was $\$ 2.4$ billion to $\$ 4.1$ billion, based on the 1976 general price level but (appropriately) at the average of the 1973 and 1976 ratios of the price of energy to the general price leve]. ${ }^{108}$

Because Perry is interested in output per hour worked rather than output per unit of input (and also to avoid explicit estimates of elasticities of substitution), he uses a variant of the income share approach at this point. He reasons as follows:
"Even if business is assumed to have accomplished all this saving by substituting labor for energy, not much extra labor could have been used in this process. $\$ 4.1$ billion is 0.5 percent of employee compensation in the business sector. $\$ 2.4$ billion is 0.3 percent. Since an unknown amount of the substitution must involve capital as well as labor, the added labor input would be smaller still. . . . Finally, some part of the energy saving must have involved no substitution of other inputs at all: lowering thermostats to 68 degrees in winter and raising them to 75 degrees in summer or turning out every other light in hallways are obvious examples, but there must have been less obvious examples of 'waste' that were eliminated only after the OPEC crisis made firms more energy conscious . . . I know of no way to pin down the answer more accurately; but on the basis of the evidence here, it seems unlikely that higher energy prices have caused more than a 0.2 percent loss of labor productivity and potential output between 1973 and 1976." ${ }^{109}$

When Perry reduced the initial 0.3 or 0.5 percent to 0.2 percent in order to obtain the effect of the higher energy price on labor productivity (output per hour) he took into account both the substitution of capital for energy and the conservation of energy without loss of production. To estimate the effect on
output per unit of input (my objective here), only the second reduction should be made. A reduction from a midpoint 0.4 -percent estimate to 0.3 percent is reasonable for 1976 . This would mean that higher energy prices reduced the growth rate of the residual from 1973 to 1976 by 0.1 percentage points. This is a significant amount, but less than one-twentieth of the drop for which an explanation is needed.

The conclusion that output per unit of input would be cut 0.3 percent by a 3.9-percent reduction in energy use in nonresidential business (the midpoint of Perry's estimates) is broadly similar to-indeed, even above-two other estimates. Ronald G. Ridker, William D. Watson, Jr., and Adele Shapanka, all of Resources for the Future, wrote: ". . . we believe that the following rule will prove to be in the ball park. According to this rule, a 10 percent reduction in net industrial and commercial energy use per unit of output, over what would otherwise have occurred had the pre-1973 trend in the ratio prevailed, results in a 0.5 percent decline in GNP during a transition period of ten to fifteen years." ${ }^{110}$ William W. Hogan and Alan S. Manne of the Institute for Energy Studies at Stanford University estimated the decline in output would be 0.4 percent from a 10 percent reduction in energy. ${ }^{111}$ Moreover, the President's Council of Economic Advisers points out that the shortterm effect is less than the longer term effect. "Widespread declines in productivity growth rates would only occur as adjustment of production methods to economize on energy took place. Actually, adjustment to the new oil prices has been extremely slow." ${ }^{112}$

Before Perry's study, Robert H. Rasche and John A. Tatom of the Federal Reserve Bank of St. Louis estimated that the increase in the price of energy permanently reduced economic capacity, or potential output, by 4 to 5 percent. ${ }^{113}$ This would mean a reduction of 5 or 6 percent in potential nonresidential business national income and in my residual series. Their estimate flowed from what are, conceptually, two equations. One assumes that the elasticity of demand for energy used in production is unity, so that each 10 -percent increase
in the price of energy relative to the price of output reduces energy input by 9.1 percent. The other assumes a Cobb-Douglas-type of production function, in which energy is treated as an input along with labor and capital. Energy is given a weight of 12 percent, so each drop of 9.1 percent in energy consumption reduces GNP by 1.1 percent. Lacking data on energy consumption, Rasche and Tatom condensed the two equations, estimating that each 10 percent increase in the relative price of energy reduces output by 1.1 percent.

Although the condensation of the equations eliminates the calculation of energy input, it is easy to calculate that the assumption of unit elasticity of demand implies that the 57 -percent increase in the relative price of energy from 1973 to 1976 reduced energy use by 36 percent relative to what it would otherwise have been (since $100 \div 1.57$ $=64$ ) The Rasche-Tatom estimate of the productivity loss assumes that this actually happened. Although the size of the actual reduction is uncertain, it is obvious that it did not remotely approach such a magnitude. Rasche and Tatom radically overestimated the size of the quantity response to the price increase. A second reason the RascheTatom result is so high is their use of a 12-percent weight for energy, which they based on "a finding that the share of energy costs in total factor costs" was quite stable throughout the 1960 's at around 12 percent of total factor costs. The estimate cited refers only to manufacturing. ${ }^{114} \mathrm{It}$ is far above any of the estimates for nonresidential business or the whole economy that I have located.

If Perry's estimate that the use of energy was reduced by 2.9 to 4.9 percent were substituted for the implied Rasche-Tatom estimate of 36 percent, and if Brinner's 5 percent weight were substituted for their 12 percent, then the second Rasche-Tatom formula would yield 0.14 to 0.25 percent as the reduction in output per unit of input in 1976 that stemmed from the energy price increase. ${ }^{115}$

Another sizable estimate has recently appeared. Edward A. Hudson of Data Resources, Inc., and Dale W. Jorgenson of Harvard University analyzed the
impact of higher energy prices by using their "dynamic general equilibrium model of the U.S. economy." ${ }^{116}$ A feature of the model is its reliance on a close relationship between the quantity of capital and energy use-that is, energy and capital are considered complements with a low elasticity of substitution between them. But a high degree of substitution is thought to exist between energy and capital, on the one hand, and labor, on the other. The model "was used to simulate two economic growth paths over the 19721976 period. In the first simulation, actual values of the exogenous variables, including world oil prices, were employed as the basis for model solution. . . . In the second simulation, 1972 energy prices were employed over the whole 1972-1976 period." Since all other exogenous variables were the same, "the differences in simulated economic activity can be attributed solely to the impact of the oil price increase." ${ }^{117}$ These differences include the effects of the impact of the oil price increase on demand as well as on production relationships.

Their model results showed energy consumption 8.8 percent lower in 1976 with the energy price increase than without, real GNP 3.2 percent lower, and energy consumption per unit of GNP 5.8 percent lower. The energy estimates refer to all uses of energy, not just business use, so the 5.8 -percent reduction is not necessarily comparable to Perry's 2.4-4.9 percent; still, it is in the same ball park. The model showed labor input lower by 0.5 million jobs or just over 0.5 percent with the energy price increase than without it, and GNP per unit of labor 2.57 percent lower. Capital input evidently was 3.0 percent lower. ${ }^{118}$ The base to which the percentage reduction in capital refers is unclear. If it includes all nonresidential and residential business capital and land (that is, all nonlabor input) the reduction in total factor input is about 1.23 percent because the weights, gross of depreciation, in the economy as a whole, are about 0.72 for the drop of something over 0.5 percent in labor and 0.28 for the 3.0 percent drop in "capital." 119 With total energy use reduced 8.8 percent, energy per unit of
factor input is lowered by 7.7 percent. With GNP reduced 3.2 percent, GNP per unit of factor input is lowered by 2.0 percent. If as seems reasonable, 1973 GNP was unaffected, the rise in energy prices would than have reduced the growth of GNP per unit of input in the whole economy by almost 0.7 percentage points from 1973 to 1976.

The implied drop of 2.0 percent in GNP per unit of labor, capital, and land as the result of a mere 7.7-percent decline in total energy consumption per unit of labor, capital, and land is puzzling. The value of energy used in nonresidential business does not exceed 4 percent of total factor input in the whole economy. Suppose business use of energy fell by the same percentage (7.7) per unit of input as total use. The usual procedure would then yield a reduction in output per unit of labor, capital, and land of only 0.3 percent ( $7.7 \times 0.04$ ). Hudson and Jorgenson obtain a result seven times as large. The disparity is partly due to different estimates of elastioities of substitution, but it does not seem that this could be the whole explanation. Both the difference in elasticities and the cause of the remainder of the difference need more explanation than has been made available.

My citation of several studies may create the false impression that the scale of investigation of the effect of the energy price increase on past output has been substantial. In fact, study of the actual effect of the change in the energy situation on total output and productivity since 1973 is miniscule even in comparison with the resources devoted to trying to guess at its implications for the 21st century. More research specifically devoted to measuring the effects already experienced is needed. Pending such research, the estimate that the energy price increase reduced the growth rate of my residual by about 0.1 percent a year from 1973 to 1976 is reasonable.

## The "shift to the services" and other structural changes

Whenever productivity is discussed at any length, someone will assert that opportunities to raise productivity are less for services than for commodities,
that the service share of the economy is rising rapidly, and that the overall rate of productivity advance most therefore decline. I examined this allegation in a long article in 1973 and concluded that within the nonfarm nonresidential business sector it simply has no substance. ${ }^{120}$ The most obvious, although not the only, reason is that within this sector there was no appreciable shift to the services. This is so whether one considers employment classified by industry or output classified by end product. The shift of employment from farming to other commodity and service industries did affect productivity. Because the shift reduced misallocation, its effect was favorable and its diminishment therefore unfavorable. But the amount was estimated in the present study and is excluded from my residual series.

In the same article I stressed that a classification based on commodities and services is in any case inappropriate because industries or products classified iu each group are completely lacking in homogeneity with respect to productivity change-or to almost anything else. Both groups contain industries of fast and slow productivity growth.

The Bureau of Labor Statistics has also explored the effect of the shift to the services. Jerome A. Mark, its Assistant Commissioner for Productivity and Technology, noted in testimony before the Joint Economic Committee that services can be defined very narrowly, to include only business or personal services, or (as I defined them) very broadly to include all noncommodity producing industries. In either case the effect of the shift was trivial. Under the narrow definition the effect of shifts in hours to the services was -0.01 percentage points in 1947-76, zero in 194766 , and -0.02 in 1966-76. By the broad definition it was slightly positive: 0.01 percentage points in 1947-76, zero in 1947-66, and 0.04 in 1966-76. ${ }^{121}$

Quite apart from such calculations and the inappropriateness of a com-modity-service dichotomy, in the article previously cited I raised "a fundamental objection to the procedure of analyzing the behavior of components in the past in order to judge future productivity
trends within nonfarm nonresidential business. The objection is to the implicit assumption that components which gain or lose share of employment or total input, and which have above average or below average productivity gains in one period, will have the same characteristics in the next period." ${ }^{122}$

I went on to say:
"Suppose we classify nonfarm nonresidential business or a major portion of it by detailed components, whether by industry or by end product. Available evidence suggests that over any time span that is long and terminated by years that are representative we are likely to find that employment and other input measures increased by an above average amount in components whose productivity increased by an above average amount. This is not really surprising. One reason is that components toward which demand shifts secure the greatest productivity gains from economies of scale. Another is that new components typically both increase their shares and have large productivity gains. A third is that demand appears typically to be so elastic that declining relative prices resulting from above average productivity gains raise volume more than enough to offset the saving in employment and other inputs that results from above average productivity gains." ${ }^{123}$

And finally:
"If this relationship holds, components with above average productivity gains during a period will be found to have bigger shares of employment or total input at the end of a period than at its beginning. Does this mean we should expect ever-rising rates of productivity growth in the sector as a whole? Of course not. Such a tendency would be present only if at every date the components which had high rates of productivity gain and increased their shares of input or employment in previous periods will again have high rates of productivity gain, and increase or at least not reduce their shares, in the period to come. There is no such continuity. Industries rise and fall.
"Suppose, instead, that in some period or by some classification the relationship is the opposite: that components with fast-rising productivity in a period
systematically lose their shares of inputs. Would this mean an ever-falling rate of productivity increase? No, for the same reason." ${ }^{124}$

## Possible errors in the data

The change in the course of NIPPE was so sudden and sharp after 1973 that some observers have wondered whether it really happened. They ask whether some development might have introduced a sudden error into the output measure.

An error in real output could result from an incorrect series for output valued in current prices or from errors in price data used for deflation. Output (national income) in current prices is measured in two ways. In one, GNP is first estimated, as the sum of expenditures for final products (personal consumption expenditures, gross private domestic investment, net exports, and government purchases). To obtain national income, capital consumption, indirect business taxes, and business transfer payments are then subtracted from GNP and subsidies are added. The second way, on which my series is based, is to add the several types of earnings from current production (employee compensation, proprietors' earnings, rental income of persons, corporate earnings, and net interest). The two estimates agree rather well from 1973 to 1976.

There is, nevertheless, one reason to suspect that national income in current prices may be unusually subject to error in 1973-76. It pertains to the inventory valuation adjustment, which enters into the estimates obtained by both methods. ${ }^{125}$ Estimates of inventory valuation adjustment are needed to obtain the change in nonfarm business inventories (a component of gross private domestic investment, which enters into the first estimate) and nonfarm proprietors' earnings and corporate earnings (components of the second estimate). The inventory valuation adjustment is difficult to measure and it was unusually big from 1973 through 1976 as the result of large price movements. It the same time, difficulties in its estimation were increased by widespread changes in business accounting practices (shifting from first-in-first-out
to last-in-first-out accounting). As a result, output in current prices was more susceptible to measurement error, in either direction, than usual. Even so, an error in the current-dollar figures large enough to alter the productivity picture materially would surprise me greatly. With respect to the possibility of systematic downward bias in the current-dollar series after 1973, I am not aware of any development likely to lead to such a bias.
The price data used for deflation are ordinarily subject to greater error than the current-dollar measures. The period under discussion was one of unusually large price change, and this may have made the data unusually prone to error. I do not know that price indexes are subject to greater error when prices are changing sharply than when they are relatively stable, but such a relationship seems plausible. For some components of fixed investment and government purchases from business there may be timing discrepancies between a price index and the current-dollar figure it is used to deflate; the former, for example, may refer to new contracts, the latter to deliveries or work done. Error from timing mismatches becomes more difficult to avoid if prices fluctuate widely.
In the period under review there is also a special consideration: Price data may have been affected by price controls. Price controls tend to cause understatement of reported prices, which would cause measures of real output to be overstated. Controls of fluctuating severity were in effect from August 15, 1971, through April 1974. Consequently output in this period may be overstated relative to earlier and later years. This would make the 1969-73 growth rate too high and the 1973-76 rate too low. If 1973 prices were understated by onehalf percent, for example, the growth rates of output and the residual would be 0.13 percentage points too high in 1969-73 and 0.17 points too low in 1973-76. Unless the price bias were bigger ihan this, the retardation in the growth rate of the residual would still be confined to the 1973-76 period. ${ }^{126}$

The Federal Reserve Board Index of Industrial Production is sometimes compared with components of real GNP that roughly correspond to its cover-
age. ${ }^{127}$ With respect to changes from 1973 to either 1976 or 1977, and based on the data available at the end of 1978, the series happen to be in close agreement; the Industrial Production Index actually yields growth rates slightly (about 0.1 percent a year) lower than the GNP series. ${ }^{128}$

There is no way to determine the accuracy of the output data conclusively; only impressions can be offered. Mine is that statistical errors in output measurement may have contributed something to the observed productivity slowdown, but it is improbable that they contributed very much.

The growth rate of NIPPE would be affected by errors in employment data as well as in the output series, except to the extent that inconsistencies are eliminated by measuring current-dollar output by adding the several types of earnings from current production. ${ }^{129}$ The growth rate of the residual would also be affected by noncompensating errors in the series measuring effects of other determinants. Random errors in these series, if not offsetting, consequently could cause the amount of retardation in the residual to be overstated-or understated. ${ }^{130}$

It is sometimes suggested that growth of an illegal economy, or a barter economy, has caused a large amount of production to disappear from the scope of the output measure. I have not been able to visualize how this might have occurred in such a way as to instill a sudden sharp downward bias in output per unit of input when output is measured by adding the several types of earnings from current production.

## Summary and Clues

Seventeen suggested reasons for the slowdown in my residual series have been explored. I rejected a few suggestions, expressed skepticism about some, had no opinion about others, and characterized the rest as probably correct but individually able to explain only a small part of the slowdown. No single hypothesis seems to provide a probable explanation of the sharp change after 1973.

It is possible, perhaps even probable, that everything went wrong at once

Table 2.-GNP in 1973 in Constant (1972) Prices and Growth Rates of GNP Per Hour Worked, 1948-73, 1973-76, and 1973-78, by Industry ${ }^{1}$

1. Denominator of GNP per hour worked excludes hours worked by unpaid family workers.
2. Excludes finance, insurance, and real estate; private households; and government and government enterprises 3. Classification for 1948-73 growth rate differs slightly from classification used for 1973-76 and 1973-78 rates.
3. Excludes private households; includes nonprofit institutions.

Sources: Calculated from national income and product account tables 6.2, 6.11, and (to eliminate hours in private households) 8.10 .
among the determinants that affect the residual series. Many determinants whose effects were directly estimated contributed to the drop in the growth rate of NIPPE from 1948-73 to 197376 , and the rest of the drop may have resulted from a large number of the explanations explored here, with each subtracting one- or two-tenths of a point from the growth rate. Several developments may have combined to slow the advance in knowledge itself, and others to retard incorporation of new knowledge into production. Similarly, inflation, regulation, soaring energy prices, high taxes, and changing
attitudes may have conspired to exert a large adverse impact upon the miscellaneous determinants of output that forced the residual series into an actual decline.

The finding that the unexplained slowdown in productivity growth started only after 1973 not only is in itself an important clue to the causes of the slowdown but also permits one to arrive at another: The retardation was typical of the main industrial branches of the economy rather than focused in one or two areas for which one might seek special explanations. ${ }^{131}$ Table 2 compares the rates of real GNP per

Table 3.-Selected Growth Rates in Industrial Countries, Selected Periods

hour at work in 1948-73 with the rates from 1973 to both 1976 and 1978. In 10 of the 11 branches, including both nondurable and durable goods manufacturing, the growth rates of GNP per hour in both 1973-76 and 1973-78 were much below the 1948-73 rate. ${ }^{132}$ The only exception is communication (mainly the telephone industry). ${ }^{133}$ It seems safe to infer that the decline in the residual was also general.

International comparisons provide an opportunity to obtain still another clue. To do so, however, it would be necessary to develop up-to-date estimates of the sources of growth in other advanced countries comparable to mine for the United States. ${ }^{134}$ If the residual series for other countries showed no retardation, it would suggest a localized cause for the decline in the United States. But if most other countries experienced a similar setback, this would strengthen the case for causes (such as inflation) that have been widespread.

The top panel of table 3 compares growth rates of output per employed civilian in the whole economy in the

United States and six other large industrial countries. In the United States the growth rate per employed civilian dropped by about 2 percentage points from either 1950-73 or 1960-73 to either 1973-76 or 1973-77. The rate also dropped in all six other countries shown. The drop was smaller than in the United States only in Germany. It was about the same in Canada, France, and the United Kingdom. In Japan and Italy it was much larger. It should be called, however, that all these countries shared in the world recession after 1973.

The bottom of table 3 compares output per hour in manufacturing in 197376, 1973-77, and 1973-78 with rates in 1950-73 and 1960-73 for 10 countries besides the United States. Among the six large foreign countries, all except Germany experienced an unambiguous drop in the rate. The drop was less than in the United States in France and larger in Canada, Japan, Italy, and the United Kingdom. Among the four smaller countries, the rate dropped sharply in Sweden. If the recent years are compared with $1960-73$, the rate
also dropped appreciably (though much less than in Sweden) in Denmark and the Netherlands, but not very much in Belgium.

These data show that sharp declines in the growth rates of NIPPE and of output per hour in manufacturing were widespread. They do not prove that this pattern carries over to the residual, but it may. It would be worthwhile to find out. ${ }^{135}$

Another way to learn more about the causes of the slowdown in the residual is to investigate intensively the suggestions I have reviewed in this chapter. Although some are not readily amenable to research, many are, and properly focused investigations on each of them would be valuable.

Finally, the mere accumulation of experience as time elapses will be helpful. The residual series may regain its lost ground, resume its old growth rate at the new lower level, or assume a lower growth rate from this lower level. Knowledge of the actual path over the next few years should assist in the identification of causes.

## Footnotes

18. I have discussed this important aspect of output measurement more extensively in earlier books. See especially The Sources of Economic Growth in the United States and the Alternatives Before Us (New York: Committee for Economic Development, 1962), pp. 155-57 and 231-46. Hereinafter cited as The Sources of Economic Growth.
19. Ibid, pp. 239-46.
20. "Research Expenditures and Growth Accounting," in B. R. Williams, ed., Science and Technology in Economic Growth (New York: Halsted Press for the International Economic Association, 1973).
21. He also estimated that if R. \& D. were capitalized instead of expensed, the growth rate of output and the contribution of $R$. \& D. would both be 0.2 percentage points higher.
22. The largest sample of cases for rates of return has been built up by Edwin Mansfield of the University of Pennsylvania and his associates. See Edwin Mansfield and others, "Social and Private Rates of Return from Industrial Innovation," Quarterly Journal of Economics, vol. 91 (May 1977), pp. 221-40. See also Edwin Mansfield, "Research and Development, Productivity Change, and Public Policy," in Relationships between $R$ and Dand Economic Growth/Productivity (National Science Foundation, November 9, 1977).
23. Kendrick, "Total Investment and Productivity Developments."
24. In "Research Expenditures and Growth Accounting," p. 80, Griliches says that "if one expands the boundaries of the relevant concept of R. \& D., one should probably adjust the
estimated rates of return downward accordingly. . ." (Kendrick does not do so.) If one adopted this alternative, he would need to use a higher rate of return in the 1970's than in the 1960's because the proportion of R. \& D. that is largely irrelevant declined. Kendrick actually uses a lower rate in 1966-73 than in 1948-66, and this contributes to the decline in his estimate of the contribution.
25. I disregard in this article attempts to ascertain the results of R. \& D. spending on the economy as a whole by correlation analysis because results are too tenuous. Problems are lescribed in Zvi Griliches, "Issues in Assessing the Contribution of Research and Developzent to Productivity Growth," Harvard Institute of Economic Research Discussion Paper 41 (August 1978). For a comprehensive discussion of efforts to arrive at results of $\mathbf{R}$. \& D., see all the papers (by Edwin Mansfield, M. Ishaq Nadiri, Nestor E. Terleckyj, George C. Eads, and John W. Kendrick) in Relationship Between $R$ \& $D$ and Economic Growth/Productivity. 26. Roger Brinner, Technology, Labor, and Economic Potential (Lexington, Mass.: Data Resources, Inc., 1978), p. 102.
27. Whether obsolescence should be deducted at all in calculating the contribution of R. \& D. to growth is a question that need not be resolved here, but I shall note that such a deduction seems questionable to me (except when obsolescence results from demand shifts rather than new knowledge). This is because the social rates of return used in such calculations are based on comparisons of the output obtained when the fruits of an R.\& D. project are available with the output obtainable from the same inputs when the fruits of that project are not available but all other existing knowledge, including any made obsolete by the new knowledge, is avail able. If R. \& D. expenditures are multiplied by such a net rate of return to obtain the increase in output that they permit, where is the overstatement that the obsolescence deduction is meant to eliminate?

31. Bradley Graham, The Washington Post. Sentember 3. 1978.
32. Giarini, "Economics, Vulnerability and the Diminishing Returns of Technology," p. 18. 33. Margiloff says that a decline in the public's expectation of technological innovation has led society to seek to moet problems by turning to financial solutions (pouring in money) and to improvements in management technique. Technology, he laments, has been left to set its own goals without guidance from the public, with adverse effects on productivity He argues that it is possible to identify desired rates of change of productivity, particularly in manufacturing and construction, and that a suitable structure of recognition for achievements in these directions would result in having professionals strive to meet these needs, rather than less socially important ones that often enjoy more public and professional acclaim. He contrasts the great advances in the art of construction during the 19th century with their absence in the 20th. He points to a lessened attraction of engineering for the brightest young people, relative to the sciences. He regrets the absence of awards for technology comparable to the Nobel prizes for science and reports that the American Institute of the City of New York "was founded to spur the development of what we now call civilian technology and did so for about a hundred years." About 50 years ago the institute dropped activities that related to technology and began to sponsor the high school science fairs, no longer participating "in spurring or rewarding in any way the development of technology, which was its original function." Other organizations acted in much the same way. But it seems clear that the developments Margiloff describas are very long run and would not have produced a sudden recent change in productivity. (Irwin B. Margiloff, "When Technology Falters," address to the 142nd Annual Meeting of the American Institute of the City of New York, February 4, 1970, and correspondence with the author.)
Tesar reports that companies had hired expert designers from central Europe to compensate for American inactivity in machine science during the first half of the 20th century but that they no longer do so. He states that machine science never enjoyed a significant portion of research funding even in periods of research expansion; the National Science Foundation supported little basic research in mechanical engineering and mechanics. According to Tesar, the weakness of U.S. mechanical technology is especially damaging currently in the field of high-quality consumer products and in light industry. (Delbert Tesar, "Mission Oriented Research for Light Machinery," Science, vol. 201 (September 8, 1978), pp. 880-87.)

35. See Edward F. Denison, assisted by Jean-Pierre Poullier, Why Growth Rates Differ: Postwar Experience in Nine Western Countries (The Brookings Institution, 1967; hereinafter cited as Why Growth Rates Differ), pp. 145-46, and citations provided there.
36. Both the Ford and Carter administrations have been well aware of these effects and tried to minimize them when legislation permitted. For a brief discussion of some of the steps taken or recommended, see Economic Report of the President, January 1979, pp. 85-91, 94, 130-31, and 162.
37. The costs of regulation of motor vehicles, aside from recalls, do not affect the residual. See citation in note 7.
38. Robert W. Crandall, "Federal Government Initiatives to Reduce the Price Level," in Arthur M. Okun and George L. Perry, eds., Curing Chronic Inflation (The Brookings Institution, 1978), p. 183.
39. Arthur Andersen and Company, Costs of Government Regulation Study for the Business Roundtable (Business Roundtable and Arthur Andersen and Co., 1979). The concept of incremental costs differs from mine in the case of capital costs; capital outlays are counted instead of the sum of depreciation and the net opportunity cost of invested capital.
40. Commission on Federal Paperwork, A Report of the Commission on Federal Paperwork, no. 6: Final Summary Report (GPO, 1977), pp. 5, 66. The estimate, the sum of estimates for small and large firms, is based on small samples. Though crude, it is apparently the best available. Inclusion of an additional $\$ 354$ million estimated to be spent by farms (p.64) would not change the rounded aggregate.
41. A report by Peat, Marwick, Mitchell and Co., commissioned by OMB, indicated that
one-third of the government paperwork burden on small buisinessmen comes from State and local governments. A survey of small Wisconsin foundries found that 21 percent of costs allocable by level of government were for State and local governments and 70 percent for the Federal Government; the amount allocated excludes 34 percent of cost that was for consultants to ensure compliance and not divided by level of government. Efforts to Reduce Federal Paperwork, Hearing before the Subcommittee on Oversight of the Senate Committee on Government Operati ons, 94th Congress, 1st Session [GPO, 1976], pp. 27, 53.
42. This is a rough estimate that I derived from Paperwork and Red Tape: New PerspectivesNew Directions, A Report to the President and the Congress from the Office of Management and Budget (GPO, 1978). The page references in the description that follows refer to that report.
An estimate of 465 million hours as of March 31, 1977, was obtained as the sum of the following components: one-fourth, including farms (p. 15), of 126 million hours (p. 34) to complete forms for departments and agencies subject to OMB review; 95 percent (assumed) of 237 million hours (p. 14) for Internal Revenue Service (IRS) forms W-2 (wage and tax statements for employees), 941 (employers' Federal tax return for employees) and 1099 (recipients of interest and dividends); one-tenth (assumed) of 149 million hours (p. 14) for IRS form 1040 (individual income tax long form); none of 33 million hours ( $p .14$ ) for IRS form 1040A (individual income tax short form); three-fourths (assumed) of 184 million hours (pp. 14, 34) for other forms (including the corporate income tax) that are required by the IRS and other agencies that are exempt from review of forms; and all of 43 million hours ( $p$. 34) for forms for independent regulatory commissions and agencies subject to General Accounting Office review.
Total hours per year required of all respondents fell from 870 million as of January 31, 1977, to 785 million as of March 31, 1978 (p. 34). If hours needed for business reports changed in the same proportion, their number was 530 million as of January 31. 1977,
43. In 1965 the Subcommittee on Census and Government Statistics of the Committee on Post Office and Civil Service of the House of Representatives stated that "the wide disparity between agency estimates for minimum time required to complete a report and respondents ${ }^{\prime}$ estimates for the same report for the most part casts serious doubt on the realism of the agency estimates." Continuing, the subcommittee said that "jt can only conclude that not only are some agencies completely unrealistic concerning the cost to the public of their paperwork undertakings but, also, that-ostrich like-they would prefer not to know such costs." (Committee on Post Office and Civil Service, The Federal Paperwork Jungle: A Report on the Paperwork Requirements Placed Upon Business, Industry, and the Public by the Federal Departments and Agencies, H. Rept. 52, 89th Congress, 1st Session (GPO, 1965), pp. 45-56.) Several instances of verified understatement are cited in Commission on Federal Paperwork, "Study of Federal Paperwork Impact on Small and Large Businesses" (July 1977), pp. 35, 36, 40.
44. Testimony of Robert H. Marik, Associate Director of OMB, in Hearing on HR 16424 to Establish a Commission on Federal Paperwork, Hearing before the House Committee on Government Operations, 93rd Congress, 2d Session (GPO, 1974), pp. 34-36. Marik gave a breakdown by source of the increase of 50 percent that occurred between December 1967 and June 1974 in the reporting burden on American business caused by required forms other than tax forms. Occupational safety and health programs, expanded social ecurity (especially medicare and medicaid), manpower programs, aircraft and airport regulations, and equal opportunity led the list.
45. This fraction is based on the OMB data cited in note 42. Estimates from the Commission on Federal Paperwork, "Study of Federal Paperwork Impact on Small and Large Businesses," imply a smaller fraction, since they show IRS forms to be responsible for 75 percent of the costs to small business (tables 6 and I-3) and apparently much less for large business (p. 46). (Small business costs are about three-fifths of the estimated total.)

49. Francis A. Allen of the University of Michigan School of Law states that "criminal provisions are routinely included in most pieces of regulatory legislation" and that "there are few, if any, regulatory areas of importance in which the possibility of criminal punishment is lacking.' Regulation by Indictment; The Criminal Law as an Instrument of Economic Control, William K. McInally Memorial Lecture, Graduate School of Business Administration, the University of Michigan (1978), p. 9.
50. The number of proposed and final actions that affected the iron and steel industry and that were published in the Federal Register in a 2-year period (1974 and 1975) came to 19,464. They consisted of 333 proposed new agency regulations, 581 final agency regulations, and 13,160 final amendments to existing regulations. Many of these also affected many or most other industries. The data are from Council on Wage and Price Stability, "Catalog of Federal Regulations Affecting the Iron and Steel Industry," in Commission on Federal Paperwork, "Study of Federal Paperwork Impact on Small and Large Businesses," p. 15.
51. Manufacturers Hanover Trust, Business Report, Autumn 1977, p. 2.
52. McLaughlin rates the regulatory burden second to the tax legislation of 1969 and subsequent years (relating to capital gains taxes and qualified stock options) as a source of productivity slowdown. The quotation is from a letter to the author, dated March 7, 1978.

62. Herbert Stein, "Spending and Getting," in William Fellner, ed., Contemporary Economic Problems, 1977 (American Entarprise Institute for Public Policy Research, 1977), p. 74.
The "more recent version" to which Stein refers is that developed by Robert Bacon and Walter Eltis with respect to Great Britain. Eltis applies it to the United States and Canada as well. See Walter Eltis, "Are Canada and the United States Following Great Britain?" New International Politics, vol. 2 (July 1977).
63. Output per hour would be reduced if investment were impaired.
64. Ibid., pp. 74, 77.
65. These are based on national income and product account definitions. Percentages for 1948 and 1973 are from Stein, "Spending and Getting," p. 65. Those for 1976 and 1978 were computed from the SURVEY, vol. 58 (July 1978) and vol. 59 (March 1979).
66. Organization for Economic Cooperation and Development, "Public Expenditure Trends" (February 2, 1978), p. 13.
67. A temporary surtax raised the percentage to 26.875 in 1968 and 27.5 in 1969.
68. Both the old and new laws permitted capital losses to be deducted from capital gains. But only a token amount of capital losses could be deducted against other income (and this small benefit was halved by the 1969 act). Losses exceeding gains in one year could be used to offset gains in a future year. The government paid no interest on a backlog of capital losses waiting to be deducted from the future gains. Since there was no negative income tax, the Government made no payment to a taxpayer whose cumulatad total income (including capital gains and loss3s) was negative. Consequently, the Government is said to share in gains but not in losses.

71. Despite claims during the 1978 tax debate that repeal of capital gains taxes would raise stock values, and hence cut the cost of equity financing, by enormous amounts it really is not clear that capital gains taxation curtails total investment by business in real assets more than other taxes. In a 1978 U.S. Chamber of Commerce survey of businessmen, 48 percent said they would increase investment if capital gains taxes were reduced; 82 percent said they would do so if the investment tax credit were increased, 78 percent if the corporate tax rate were reduced, 78 percent if faster depraciation write-offs were allowed, and 71 percent if the investment tax credit were extended to structures. ("Fear of Recession Grows Stronger," Nation's Business, October 1978, p. 45.)
72. "The Significance of Our Productivity Lag," May 14, 1977.
73. As evidence of "a lessened sense of industriousness on the part of our work force," the speech cited only high and rising absenteeism and an increase in time paid for but not worked. Neither bears directly on effort while at the work place, although they may be indicative of a change in attitudes.
74. Denison, The Sources of Economic Growth, Committee for Economic Development, December 1961, p. 166. For a history of the survival of the work ethic despite changes in the character of work as factories spread, and of the perceived need constantly to denounce laziness and profligacy, see David T. Rodgers, The Work Ethic in Industrial America, 1850-1920 (University of Chicago Press, 1978).

81. I briefly discussed effort and incentives in the context of economic growth in The Sources of Economic Growth, pp. 166-69, and Why Growth Rates Differ, pp. 112-14. The literature on the general topic of influences affecting work effort is limitless. It has apparently burgeoned in the past decade as "quality of working life" has become a popular catch phrase and as the relationship between work satisfaction and productivity has received renewed interest. Two studies of interest, both of which summarize broad experience, are Raymond A. Katzell and Daniel Yankelovich, with others, Work, Productivity, and Job Satisfaction (Psychological Corporation, January 1975); and Swedish Employers' Confederation, Job Reform in Sweden (Stockholm: Grofisk Reproduktion, 1975). Whatever the relationship, work satisfaction seems not to have changed. Bernard J. White reported that "survey results over the last forty years have been remarkably consistent in finding that from $80 \%$ to $90 \%$ of working people report moderate to high satisfaction with their jobs. Only $10 \%$ to $20 \%$ report actual dissatisfaction." ("Does Bureaucracy Deserve Its Bad Reputation?" Dividend, the Magazine of the Graduate School of Business Administration, University of Michigan, Winter 1977, p. 8.)
82. For example, Robert C. Turner of Indiana University, a former member of the President's Council of Economic Advisers, considers inflation "the most serious economic threat to economic expansion in the United States" because it reduces investment incentives and may reduce the propensity of individuals to save. (Committee on Ways and Means, Tax Reductions-Economists Comments, p. 97.) George Terborgh, a leading expert on the investment process, stresses the adverse effect that inflation exerts on business earnings after tax because business, in his opinion, does not usually base prices on replacement costs and be-
cause of its effects on tax liabilities. (George Terborgh, Corporate Earning Power in the Seventies: A Disaster [Machinery and Allied Products Institute, August 1977]). Arthur M. Okun says "the gap (created by inflation) between actual, historical costs of old plant and equipment and current or predicted costs of new facilities creates agonies in capital budgeting and weakens investment." (Arthur M. Okun, "The Great Stagflation Swamp," address to the Economics Club of Chicago, October 6, 1977.)

96. I am reminded that Erik Lundberg, the Swedish economist, ascribed this role to engineers, though only those above 40 years of age. In recent years Lundberg, describing Sweden, has written about a tendency for business to select "managers that correspond to a soft type-not strong in maximizing profits and enforcing efficiency-but good at dealing with trade unions, caring for stable employment and not least in getting money (soft loans and subsidies) from Government." (Letter from Lundberg to author, February 26, 1979.)
97. Alfred Rappaport, "Executive Incentives vs Corporate Growth," Harvard Business Review, vol. 56 (July-August 1978), pp. 81-88.
98. This was observed in the Economic Report of the President, January 1977, p. 55.
99. As explained in Accounting for Slower Growth, chapter 2, this is because imports and exports are deflated separately.
100. The high price of energy and government controls presumably forced some existing capital out of use. In the absence of information about this, no reduction was made in the Bureau of Economic Analysis (BEA) capital stock series so, if this happened, the effect was to reduce growth of the residual rather than of capital input.
101. "Energy inputs represent only approximately 5 percent of total factor costs." Roger Brinner, Technology, Labor, and Economic Potential (Data Resources, Inc., 1978), p. 74.
102. It estimated primary energy use at 70 quads (a quad is $10^{15}$ British thermal units) and the average price of energy at $\$ 1.00$ per million BTU. (Nuclear Power Issues and Choices, Report of the Nuclear Energy Policy Study Group sponsored by the Ford Foundation [Ballinger, 1977], p. 49.) The Bureau of Mines and the Energy Information Administration put the average price of domestically produced mineral fuels at 85.4 cents per million BTU. (Department of Energy, Energy Information Administration, Annual Report to Congress, vol. 3: Statistics and Trends of Energy Supply, Demand, and Prices [GPO, 1978], p. 19.) Inclusion of imported fuel and hydro and nuclear power and exclusion of exports would probably bring this figure to $\$ 1.00$.

113. Robert H. Rasche and John A. Tatom, "The Effects of the New Energy Regime on Economic Capacity, Production, and Prices", Federal Reserve Bank of St. Louis Review,
vol. 59 (May 1977), pp. 2-12; and idem., "Energy Resources and Potential GNP," Federal Reserve Bank of St. Louis Review, vol. 59 (June 1977), pp. 10-24. The range cited is from the introduction to the first article. Slightly different results based on different periods and data are provided elsewhere in these articles.
In the same articles Rasche and Tatom present a potential output series. To avoid misunderstanding, I stress that my disagreement with them is not over their conclusion that growth of potential output was sharply curtailed after 1973, but with their attribution of the change to the higher price of oil.
114. The particular use made of the estimate by Rasche and Tatom is in an analysis of manufacturing, but the manufacturing results are applied to the whole economy.
115. An interesting feature of the Rasche-Tatom analytical framework is that the output reduction is the result of a change-not of an increase-in the relative price of oil. A decrease in the price of oil would have had the same effect. A change in the relative prices of labor and capital, in either direction, also reduces output in this framework, as the authors clearly realize, since they calculate the cost of such a change. All this is rather baffling because the authors do not have in mind temporary costs of adjustment. On the contrary, they insist that the impact of the oil price increase on the American economy is "profound and permanent." Given that any change in either direction reduces output, one might expect that productivity would drop again if the price of oil were now to fall, but in another puzzling sentence the authors state that the only way potential output could be restored is for the relative price of oil to return to its old level, a statement that in another context would seem entirely reasonable.
116. Edward A. Fudson and Dale W. Jorgenson, "Energy Prices and the U.S. Economy, 1972-1976," Data Resources U.S. Review (September 1978), pp. 1.24-1.37.
117. Quotations appear in ibid., p. 1.25 .
118. In the Hudson-Jorgenson calculations, the 3.2-percent drop in GNP would in itself cause a proportional 3.2-percent drop in the demand for and use of "capital services," and therefore a 3.2-percent drop in capital stock. The drop in capital services from this cause is valued at $\$ 15.5$ billion. However, the higher energy price induces changes in the composition of demand and substitutions among labor, capital, and energy that provide a small offiset, reducing the drop in capital services to $\$ 14.5$ billion. Hence the percentage drop in capital services and capital stock was 3.2 percent $\times 14.5 \div 15.5$, or 3.0 percent.
119. The calculation is $(0.72 \times 0.54) \div(0.28 \times 3)=1.23$. If the percentage reduction in capital refers only to fixed residential and nonresidential capital, which seems likely, the reduction in total factor input in the economy as a whole is less.
120. Edward F. Denison, "The Shift to Services and the Rate of Productivity Change," Survey, (vol. 53, October 1973), pp. 20-35.
121. Jerome A. Mark, "Productivity Trends and Prospects," Special Study on Economic Change, Hearings before the Joint Economic Committee, 95th Congress, 2d Session (GOP, 1978), pt. 2, p. 485.
122. Ibid., p. 34. The reasoning applies equally to a comparison of two past periods.
123. Ibid. "Both (W. E. G.) Salter and (John) Kendrick found that industries that reduced factor input per unit of output most also reduced materials input per unit of output most. This is important in explaining the finding, because factor inputs are only part of the total costs of an industry and a given percentage reduction in factor input costs alone would yield a much smaller percentage reduction in price."
124. Denison, "The Shift to Services," p. 34. In the same article I explain why it is a mistake to suppose that within nonresidential business the accuracy of series for commodity-producing industries is greater than that for service-producing industries.
125. The inventory valuation adjustment is the difference between (1) the change in the physical volume of inventories valued in prices of the current period and (2) the change in the value of inventories reported by business.
126. A discussion of other potential biases in prices series used in deflation that might have caused overstatement of the decline in real output in 1974-75 is found in the appendix to

Victor Zarnowitz and Geoffrey H. Moore, "The Recession and Recovery of 1973-1976," Explorations in Economic Research, Occasional Papers of the National Bureau of Economic Research, vol. 4 (Fall 1977), pp. 471-557. To affect the 1973-76 movement of the residual, such a bias would have to affect the output series differently than in previous cyclical swings (otherwise it would be picked up in the series for intensity of utilization) and, to have an appreciable effect, would also have to affect price movements in the downswing without being offset in the recovery. None of the suggestions offered seem likely to qualify.
127. The GNP series includes all "goods" components, personal consumption expenditures for electricity and gas, and 40 percent of structures, minus gross farm product and margins on the sale of used cars.
128. The relative position of the intervening years differs substantially, with industrial production showing 1974 higher and 1975 lower relative to 1973 and 1976 than does the GNP series. 129. See Accounting for Growth, pp. 164-65.
130. The depth of the 1974-75 recession dropped my index for intensity of utilization due to fluctuations in demand below the previons range of experience (in the period for which it has been calculated). If its drop was underestimated, this would cause the residual to be underestimated in those years. But if that were the cause of the 1974-75 drop, it should have been followed by an exceptually strong advance in the recovery period, which did not happen.
131. Edward F. Renshaw used the same body of data to reach a similar conclusion in "A Note on the Aggregate Learning Curve for the U.S. Economy and the Persistent Gap Between Actual and Potential GNP" (1978).
132. Government and government enterprises; finance, insurance, and real estate; and private households are excluded because the data have no independent meaning and are chiefly outside nonresidential business. Nonprofit institutions were not eliminated, and this accounts for the low 1948-73 growth rate in services.
133. By dividing the postwar period at 1967 instead of 1973 and comparing 1950-67 with 1967-77, the Council on Wage and Prlee Stability concluded from the same data source that a reduction in the growth rate of productivity did not occur in manufacturing, but was confined to construction and most of the service divisions. (Council on Wage and Price Stability, Executive Office of the President News, October 4, 1978.) Even if one were concerned with longer periods such as those the Council examined, the Council's conclusion would be questionable because the result was entirely dependent on the exact choice of periods. If the Councll had divided the period at 1965, 1966, or 1968 instead of 1967 , it would have obtained a decline in the growth rate of manufacturing productivity, and the declines would have been larger if the period had begun in 1948 instead of 1950. To illustrate with an extreme case, the growth rate of output per hour in manufacturing dropped by 0.74 percentage points from 1948-65 to 1965-77 according to the series the Council used.
Jerome Mark has shown that the decline in the rate of growth of output per hour from 194766 to 1966-76 was general among 62 detailed industries for which the Bureau of Labor Statistics published series. Forty-six had lower growth rates of output per hour in 1966-76 than in 194766, one had the same rate, and 15 had higher rates. (Mark, "Productivity Trends and Prospects," p. 484.) An unpublished compilation provided by Mark in February 1979 also shows that 53 of 74 industries had lower growth rates from 1973 to 1977 (or 1976 if 1977 was not available) than from 1947 (or the earliest subsequent date for which the series was available) to 1973. The proportion was the same, three-fourths, in manufacturing and nonmanufacturing industries.
134. My study for eight Western European countries ended with 1962 (Why Growth Rates Differ), that for Canada by Dorothy Walters with 1967 (Canadian Growth Revisited, 1950-67, Staff Study 28 [Economic Council of Canada, 1970]), and that for Japan by William Chung and me with 1971 (How Japan's Economy Grew So Fast).
135. The adjustment for intensity of utilization is likely to be very difficult in several countries because it has become increasingly difficult or expensive to lay off unneeded workers. A decline in demand is likely to be matched to a lesser extent by a drop in input and to a greater extent by a drop in output per unit of input than was formerly the case or is now the case in the United States.

# State Dififerences in Per Capita Personal Income Growth in the Seventies 

IN the seventies, State differences in per capita personal income narrowed, as they have in every decade since 1930. From 1969 to 1978, per capita personal income increased at a rate that was 15 percentage points slower in the highincome States than in the low-income States. ${ }^{1}$ In the high-income States (which include the District of Columbia), per capita personal income relative to the national average declined from 114 to 112 percent, while in the lowincome States, it increased from 86 to 91 percent. The sharply reduced disparity among States in per capita personal income during the seventies reflected the surge in industrial growth of the South and West relative to the Northeast-Great Lakes manufacturing belt. Charts 2 and 3 show State per capita personal incomes for 1969 and 1978, respectively.

Among the 14 high-income States, 11-including 9 States in the NortheastGreat Lakes manufacturing belt-had below-average increases in per capita income, or, as in Michigan, an average increase (table 1). In the nine manu-facturing-belt States, per capita income relative to the national average declined substantially-from 114 to 108 percent. The largest declines were in New York and Connecticut. Each of the nine had below-average increases in

1. The timespan is from the national cyclical peak year nearest 1970 to the most recent year for which State per capita personal income estimates are available. States are divided into high-income and low-income groups based on per capita personal income relative to the national average in 1969 (see table 1).

Table 1.-Per Capita Personal Income, 1969-78

both components of the per capita income quotient-personal income and population. Manufacturing employment declined, and employment growth in other industries with relatively high earnings per worker slowed.

Three high-income States and the District of Columbia had above-average increases in per capita income. Alaska, Nevada, and Washington had aboveaverage increases in both personal income and population; employment growth was strong in construction, services, and manufacturing. The District of Columbia had a below-average increase in total personal income but a more than offsetting decline in population.
Among the 36 low-income States, 31 -including all of the States in the Southeast, Southwest, Rocky Moun-
tain, and Plains regions-had aboveaverage increases in per capita income or, as in Indiana and Missouri, an average increase. All of the Southwest, Rocky Mountain, and Southeast States except West Virginia had above-average increases in both personal income and population. Employment increased rapidly in construction, coal mining, and manufacturing, where earnings per worker are relatively high. Moreover, rapid increases in property incomespecifically, in the imputed rental income on owner-occupied dwellingsreflected the large increases in both the number of housing units and their values in the fast-growing population centers of the South and West. All of the Plains States except Missouri had above-average increases in personal income and below-average increases in
population. Continued technological change in agriculture increased income per worker in the Plains and reduced agricultural employment; this reduction was only partially offset by an increase in nonagricultural employment, and net population outmigration ensued.

Five low-income States-including four in New England-had belowaverage increases in per capita income. Reflecting the migration of workers from central and southern New England to northern New England, New Hampshire, Vermont, and Maine had unusually large increases in population. Relative to the U.S., the growth of population outpaced the growth of personal income, thereby dampening the growth of per capita income in these three northern New England States.

Table 1.-Total Personal Income,

## State Personal Income, 1958-78

AANNUAL estimates of State personal income are presented in this article on a consistent basis for the 21year period 1958-78. Revised 1978 estimates and estimates for 1958-70 that incorporate the 1976 national benchmark revisions are presented for the first time. Previously State estimates incorporating the benchmark revisions were available only back to 1971. Estimates for 1973-77 which had been presented previously, are revised. A discussion of the State benchmark revisions appears in the August 1977 Survey of Current Business, and discussion of the benchmark revisions of the national income and product accounts appears in Part I of the January 1976 Survey.

Personal income is the current income received by residents of an area from all sources. It is measured after deduction of personal contributions for social security, government retirement, and other social insurance programs but before deduction of income and other personal taxes. It includes income received from business, governments (Federal, State, local and foreign), private households, and institutions. It consists of wage and salary disbursements, various types of supplementary earnings termed "other labor income," proprietors' income, rental income of persons, dividends, personal interest income, and government and business transfer payments. Per capita personal income is the total personal income of residents divided by the resident population.

The definitions underlying the State series are, for the most part, the same as those underlying the personal income series in the national income and product accounts. The major difference is in the treatment of U.S. citizens temporarily working on assignment abroad. The national series includes not only Federal personnel-civilian and mili-tary-stationed abroad but also-since the 1976 benchmark revisions-U.S. residents employed by private U.S. firms on temporary foreign assignment. The State series includes only persons working and/or residing in the 50 States and the District of Columbia.

Tables 1 and 2 present the estimates of total and per capita personal income, respectively, for the United States, regions, States, and the District of Columbia on a consistent basis, for the entire period 1958-78. In these tables the income flows are assigned to the State in which the individual receiving the income resides.

Table 3 presents estimates of persnnal income by type and labor and proprietors' income by industry, for the United States, regions, States, and the District of Columbia, for the years 1958, 1963, 1968, 1973, 1976, 1977, and 1978. (Estimates for the years not shown are available from the Regional Economic Measurement Division, Bureau of Economic Analysis, Washington, D.C. 20230.) Table 3 also shows the derivation of personal income by place of residence. The estimates of labor and proprietors' income are reported by industry at the point of

disbursement (establishment location). Industry definitions are not entirely consistent throughout the 1958-78 period. Estimates for 1975-78 are based on the 1972 Standard Industrial Classification (SIC). Estimates for the years preceding 1975 are based on the 1967 SIC. A consistent set of reliable estimates on the 1972 SIC basis is not possible because of problems in recon-
ciling differences in the underlying data from the unemployment insurance system for the overlap year 1975. A review of the industrial coding for employers (refiling) coincided in many States with the change in the SIC classification system. It is not possible for BEA to distinguish between the code changes due to refiling and those mandated by the change in the classification system.

4. Under the 1972 SIC code ordnance was reclassified to four 2-digit industries: fabricated metal products, electric and electronic equipment, transportation equipment and in5 .
5. Adjustment for border workers: income of U.S. residents working across U.S. borders

Includes the capital consumption adjust U.S.
7. Because of an error in nonfarm proprietors' income which could not be corrected in time
for publication, the 1978 derivation of personal income by place of residence will not add to total personal income. A corrected table will be available upon request to the Regional Economic Measurement Division.
Nore.-Estimates for years prior to 1975 are based on the 1967 Standard Industrial Classification (SIC). Estimates for 1975-78 are based on the 1972 SIC.

Table 3.-Personal Income by Major Sources,
[Millions

See footnotes on pp. 32-33.

Selected Years 1958-78-Continued of dollars]

## Alternative Estimates of Capital Consumption and Profits of Nonfinancial Corporations, 1975-78

Estimates of capital consumption and profits of nonfinancial corporations for 1975-78, based on alternative depreciation formulas and service lives and valued at historical and current cost, are shown below. The estimates for $1976-78$ incorporate the revised and updated national income and product account (NIPA) estimates that appeared in the July 1979 Survey of Current Business. Estimates for 1929-72 appeared in the March 1976 Survey; estimates for 1973 appeared in the August 1976 Survey; and estimates for 1974 appeared in the August 1977 Survey. Service lives used far nonresidential structures and equipment are 100 percent of Internal Revenue Service Bulletin $F(F), 85$ percent of Bulletin F (.85F), 75 percent of Bulletin F (.75F), and 100 percent of Bulletin F through 1940 with a gradual decrease to 75 percent of Bulletin $F$ in 1960 ( $F$ to $.75 F$ ); for residential structures, the lives are 80 and 65 years for new 1-to-4 and 5-ormore unit structures, respectively, with lives half as long as these for additions and alterations.

4. Lines 4 through 18 are equal to NIPA profits with inventory valuation adjustment and
without capital consumption adjustment (line 2, table 3) plus the capital consumption adustment based on the designated valuation, depreciation formula, and service lives (lines 2 through 16, table 2). For example, line 4 equals line 2, table 3, plus line 2, table 2 .

## Durable Goods Owned by Consumers in the United States, 1975-78

Estimates of durable goods owned by consumers in the United States for 1975-78 are shown below. The estimates for 1976-78 incorporate the revised and updated national income and product account estimates of personal consumption expenditures for durable goods that appeared in the July 1979 Survey of Current Business. Estimates for 1925-74 appeared in the March 1979 Survey.

Analysis, U.S. Department of Commerce.

[^0]:    1. The Brookings Institution, 1974.
    2. To be published by The Brookings Institution at the end of this year. Methods of estimation are little changed from those described in Accounting for Growth.
    3. The practice of using two decimal points to present growth rates and the contributions of the sources is adopted to prevent rounding errors in small numbers when sources or periods are compared. It is not meant as an indication of accuracy.
    4. Three aspects of the education component need stating even in a brief summary. First, it counts only regular, formal education (except insofar as other types of education are systematically related to formal education). Second, it measures the contribution made to output by increased skills and versatility of workers resulting from additional education when the state of knowledge in the society is given. Neither the fact that advances in knowledge permit new knowledge to be transmitted in educational institutions nor the possibility that a more educated population may advance the frontiers of knowledge more rapidly is reflected in the education estimate. Third, the size of the contribution made by education in any time period depends upon the difference between the education of persons who left employment during the period and those who entered it, not the difference between those attending school at the beginning of the period and those attending at its end.
    5. See Accounting for Growth, 1989-1969, p. 77, for the main categories. Part of the fifth category now appears in table 1 as "Changes in the legal and human environment" and therefore is no longer included in miscellaneous determinants.
    6. To the extent that they are not offsetting, some types of error in the estimates for other determinants also affect this estimate. This, of course, is not a matter of classification but of accuracy.
    7. Estimates through 1975 were published in Edward F. Denison, "Effects of Selected Changes in the Institutional and Human Environment Upon Output Per Unit of Input," Survex of Current Business, vol. 58 (January 1978). The 1976 estimate assumes the changes analyzed in the article curtailed the annual increase in output per unit of input less in 1976 than in 1975.
    8. For an explanation of the effect of variations in the calendar on productivity see Accounting for Growth, pp. 67-68 and 311-13. The fact that 1976 was a leap year that consisted of 52 weeks plus a Thursday and Friday probably raised the 1976 figure for the residual and for productivity series.
    9. "Tax Policy and the Supply Side," address before the American Economic Association and the American Finance Association in Chicago, August 29, 1978. The Secretary also pointed to regulatory costs.
    10. Thomas O'Toole, The Washington Post, June 21, 1978. The experts also referred to increased Government regulation and an outdated patent policy.
[^1]:    1. The personal income level shown for the United States differs from that in the national
[^2]:    Acknowledgments
    The personal income estimates were prepared under the direction of Edwin J. Coleman, Chief of the Regional Economic Measurement Division. The review and evaluation of methods was provided by Jeanne S. Goodman. Tables were prepared by Eunice P. James, Stuart A. Schwartz, and Kathy A. Albetski of the Regional Economic Information System Branch. Secretarial support was provided by C. Dale Lyons.

    Estimates of private nonfarm wages and salaries and other labor income were prepared under the supervision of Elizabeth H. Queen, Chief of the Private Wage and Income Branch. She was assisted principally by: David J. Albright, Carl J. Carlson, Sharon C. Carnevale, Carol E. Evans, Kevin O'Brien, Michael G. Pilot, William E. Reid, Jr., and Victor Sahadachny.

    Estimates of farm income, government wages and salaries, government other labor income, proprietors' income, property income, transfer payments, and contributions for social insurance were prepared under the supervision of Kenneth P. Berkman, Chief of the Government, Proprietary, and Investment Income Branch. He was assisted principally by: Vivian G. Conklin, Andrew E. Weiser, Gary V. Kennedy, and Jeanne O'Neill.

    Residence adjustments, disclosure-avoidance, and final preparation of the State personal income estimates were performed under the supervision of David W. Cartwright, Chief of the Regional Economic Information System Branch. He was assisted principally by Wallace K. Bailey and Paul M. Levit.

[^3]:    * Less than $\$ 500,000$.

    D Not shown to avoid disclosure of confidential information; data are included in totals. $\quad 3$. Includes wages and salaries of U.S. residents working for international organizations.

    1. Consists of wage and salary disbursements, other labor income, and proprietors' income.
