## U.S. Department of Labor Alexis M. Herman, Secretary

## Bureau of Labor Statistics Katharine G. Abraham, Commissioner

The Monthly Labor Review (USPS 987-800) is published monthly by the Bureau of Labor Statistics of the U.S Department of Labor. The Review welcomes articles on the labor force, labor-management relations, business conditions, industry productivity, compensation, occupational safety and health, demographic trends, and other economic developments. Papers should be factual and analytical, not polemical in tone.
Potential articles, as well as communications on editorial matters, should be submitted to:

Editor-in-Chief
Monthly Labor Review
Bureau of Labor Statistics
Washington, DC 20212
Telephone: (202) 691-5900
E-mail: mlr@bls.gov
Inquiries on subscriptions and circulation,
including address changes, should be sent to
Superintendent of Documents
Government Printing Office
Washington, dc 20402
Telephone: (202) 512-1800
Subscription price per year- $\$ 31$ domestic; $\$ 38.75$
foreign. Single copy - $\$ 10$ domestic; $\$ 12.50$ foreign.
Make checks payable to the Superintendent of Documents.
Subscription prices and distribution policies for the Monthly Labor Review (ISSN 0098-1818) and other government publications are set by the Government Printing Office, an agency of the U.S. Congress.

The Secretary of Labor has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Periodicals postage paid at Washington, DC, and at additional mailing addresses.

Unless stated otherwise, articles appearing in this publication are in the public domain and may be reprinted without express permission from the Editor-in-Chief. Please cite the specific issue of the Monthly Labor Review as the source.

Information is available to sensory impaired
individuals upon request:

## The March Review

Projects that integrate information across survey lines are all too rare. Thus, we are glad to lead with the analysis by Diane F. Herz, Joseph R. Meisenheimer II, and Harriet G. Weinstein of heath care and retirement benefits data from the Current Population and Employee Benefits Surveys. The article, in addition to delivering information on the incidence and characteristics of two important classes of benefits, also helps readers understand the relative strengths and weaknesses of household and establishment surveys.

Randy E. Ilg and Steven E. Haugen examine trends in employment and real earnings, both overall and in high-, medium-, and low-earnings occupational categories. They find that a modest increase in real median earnings in the 1990s was concentrated in time in the final 2 years and most evident in the low-earnings group. The high-earnings group, while it grew substantially over the decade, had only a slight increase in its earnings median. The middle category saw very little change in employment or earnings.

William C. Goodman reports on broad developments in the air transportation industry. His analysis points to an industry in which, over the long haul, prices have declined, productivity has increased, and output and employment have increased substantially.

Mark S. Handcock, Martina Morris, and Annette Bernhardt return us to working across surveys. In this case, the article works with trends in earnings inequality as measured by different household surveys. Researchers have found apparent discrepancies between a rising trend in earnings variance-a measure of increasing earnings inequality-in the Current Population Survey and a falling trend in the variance of earnings in the National Longitudinal Survey of Youth 1979. The authors find that restricting the sample to full-time, full-year workers eliminates much of the discrepancy.

## Fewer mass layoffs

There were 14,909 layoff events in 1999, involving a total of 1,572,399 initial claims for unemployment insurance in the 50 States and the District of Columbia. After increasing in 1997 and 1998, the number of layoffs and initial claimants returned to around 1997 levels.

Manufacturing accounted for 33 percent of all mass layoff events in 1999 and 40 percent of initial claims filed. Initial claims filings were most numerous in transportation equipment $(98,746)$ and industrial machinery and equipment $(87,363)$.

The number of initial claims due to mass layoffs continued to be higher in the West $(576,654)$ than in any other region. Layoffs in business services, agricultural services, and motion pictures accounted for 41 percent of the claims in the West. The fewest mass-layoff initial claims continued to be reported in the Northeast region (207,057). For more information, see "Mass Layoffs in December 1999" (USDL 00-49).

## Few work stoppages

Seventeen major work stoppages began in 1999, the lowest number in the 53-year history of the series. Of the 17 major work stoppages beginning in 1999, 12 were in the private sector; the remainder occurred in State and local government, all in educational services. In the private sector, seven stoppages occurred in goods-producing industries, and five occurred in service-producing industries.

In all, only 73,000 workers were involved in these work stoppages. This was the lowest level in the 53 -year-old series and the first time the level was below 100,000. In comparison, in 1998, major work stoppages idled 387,000 workers. This series peaked in 1952, when 2,746,000 workers were involved in stoppages. Additional information is available in "Major Work Stoppages, 1999 (USDL 00-51).

## Higher productivity

Productivity increased 2.9 percent in the nonfarm business sector during 1999 , about the same as the 2.8 percent rise in 1998. Output in nonfarm businesses rose 4.7 percent, and hours of all persons increased 1.7 percent. Unit labor costs in the sector grew 1.8 percent in 1999, somewhat less than their 2.4-percent increase in 1998. This reflected, in part, an hourly compensation rise of 4.8 percent in 1999, compared with a 5.2 -percent increase in 1998. For more information, see "Productivity and Costs" (USDL 00-64).

## Declining unemployment

Annual average unemployment rates decreased in 35 States and the District of Columbia in 1999. Unemployment declined in all four broad regions-Northeast, Midwest, South, and West-and eight of their nine component divisions.

Among the States, Maryland and Oklahoma posted the largest rate declines in 1999 ( -1.1 points each), followed by Arkansas ( -1.0 point). Four other States recorded decreases of more than three-quarters of a percentage point. (The District of Columbia's rate dropped by 2.5 percentage points.)

Among the Nation's nine geographic divisions, the Pacific division, along with the West South Central division, recorded the largest rate decrease from 1998 ( -0.5 percentage point each). The drop in the Pacific division's rate was largely due to improvements in the California labor market.

The West region recorded the largest decline over the year, down 0.5 percentage point, followed by the Northeast and South, down 0.3 point each. Unemployment in the Midwest region edged down 0.1 point. Additional information is available in "Metropolitan Area Employment and Unemployment: January 2000" (USDL 00-71).

# Health and retirement benefits: data from two BLS surveys 

#### Abstract

Both the household-based Current Population Survey and the establishment-based Employee Benefits Survey have strengths and limitations with respect to collecting information on health and retirement benefits: demographic information is best obtained from household surveys; details of benefit plans are best collected from establishments

Diane E. Herz, Joseph R. Meisenheimer II, and
Harriet G. Weinstein

Diane E. Herz and
Joseph R.
Meisenheimer II are economists in the Office of Employment and Unemployment Statistics, Bureau of Labor Statistics. Harrie† G. Weinstein is an economist in the Office of Compensation and Working Conditions, Bureau of Labor Statistics.

Employee benefits are an important aspect of job quality. In assessing the quality of different types of jobs, workers, employers, and researchers often consider benefits along with other characteristics of jobs, such as pay, job security, job safety, and the type of work involved. ${ }^{1}$ Many employers are concerned about the cost of benefits, which compose 28 percent of compensation costs for employers in the private sector and State and local governments. ${ }^{2}$ Public policymakers also frequently focus on employee benefits. For example, many observers have expressed concern in recent years about the number of Americans who lack health insurance. In response, policymakers have debated whether universal health coverage should be a national goal. Central to that debate are the role employerprovided health insurance plays in the current health care system and what role it might play in any proposed new system. Employer-provided retirement plans also have been the subject of public policy discussions. As the baby-boom generation-the huge cohort of Americans born between 1946 and 1964 -approaches retirement age, concern has arisen about whether Social Security and private pension plans can withstand the strain of providing retirement income to so many people. ${ }^{3}$

Clearly, having accurate information on employee benefits is important for workers, employers, and public policymakers. ${ }^{4}$ Two BLS surveys provide estimates of participation in employee benefits plans: the Current Population Survey
(CPS) and the Employee Benefits Survey (EBS). The CPS is a monthly survey of 50,000 households from which information is obtained on employment, unemployment, demographics, earnings, and more. The cPS is jointly conducted by the Bureau of Labor Statistics and the Bureau of the Census. The ebs obtains data from establishments on the number of participants in a variety of employee benefits plans and the detailed provisions of those plans. The ebs is being incorporated into the National Compensation Survey, which, when fully integrated, will provide measures of occupational earnings, trends in compensation costs, and participation in, and details of, benefit plans. ${ }^{5}$

This article compares information that the CPS and ebs provide on two of the most important categories of benefits: health and retirement plans. According to the CPS, 66 percent of fulltime workers in the private sector participated in a health plan provided by their employer in 1995. The ebs indicates that 71 percent of full-time pri-vate-sector workers participated in an employerprovided health plan. The gap between the two surveys is greater in regard to participation in retirement plans: the CPS indicates that 49 percent of full-time workers in the private sector participated in an employer-provided retirement plan in 1995; the comparable figure from the EBS is 60 percent.

The material that follows is intended as a guide for researchers, public policymakers, and others to understand the strengths and limitations of CPS
and EBS data on employee benefits. Among the topics examined are differences in estimates derived from the two surveys and possible reasons for inconsistencies between them. The types of information that each survey provides also are described.

## Data on prevalence of benefits

Although the cPs is a monthly survey, it does not include questions each month on employee benefits. Rather, supplementary questions on benefits have appeared periodically in the CPS since the early 1970s. CPS supplementary surveys on em-ployer-provided benefits were conducted in April 1972, in May of 1979, 1983, and 1988, and in April 1993. ${ }^{6}$ There are no current plans to repeat those surveys, but questions on health and retirement benefits were included in CPS supplements on workers in contingent and alternative employment arrangements conducted in February of 1995, 1997, and 1999. The supplementary questions were asked of all employed persons covered in the cPs. The employee benefits data from the February 1999 cPS are not yet available, so the sections that follow examine data from the February 1995 and 1997 surveys. The annual demographic supplement to the cPs, conducted each March, also contains health insurance questions, but the focus of those questions is coverage from any source, rather than employer-provided coverage. Hence, the March CPS data are not analyzed in this article. ${ }^{7}$

The ebs is actually three different surveys. In odd-numbered years, "medium and large" private-sector establishments - those with 100 or more workers - have been surveyed. In even-numbered years, "small" private-sector establish-ments-those with fewer than 100 employees-have been surveyed, as have State and local governments. The analysis that follows combines data from the two private-sector surveys1994 for small establishments and 1995 for medium and large establishments-to produce estimates for the total private sector. Data from the 1994 survey of State and local governments are combined with data pertaining to the total private sector to provide measures of the entire economy (excluding Federal employees).

The ebs excludes workers in the Federal Government, agricultural workers, self-employed persons, family members who work without pay in family-owned businesses, workers in private households, and some workers in religious and not-forprofit organizations. Such workers are included in the CPS. In order to compare CPS and EBS data on participation in employerprovided health and retirement plans, it is necessary to exclude from the CPS tabulations as many workers as possible who are outside the scope of the EBS. For this reason, the CPS estimates examined in this article generally will include wage and salary workers in the private, nonagricultural sector and in State and local governments. Excluded are Federal employees, workers in agriculture, all self-employed persons (regardless of whether their businesses are incorporated), independ-
ent contractors, and unpaid family workers.
The analysis focuses primarily on full-time workers, although benefit coverage for part-time workers is discussed briefly. The two surveys define "full time" and "part time" differently. In the EBS, respondent establishments use their own criteria to determine who is considered to be a full- or parttime employee. In the cPS, anyone who usually works at least 35 hours per week is considered a full-time worker, and those who work fewer than 35 hours are part time.

## Why two surveys on benefits?

Many readers may ask why it is necessary to have two surveys that collect information on participation in employee benefit plans. The reason is that household and establishment surveys often complement each other, because each has different strengths and limitations. Household surveys are better equipped to obtain information on workers' demographic characteristics, such as their age, sex, race, and marital status. This information typically is not collected in establishment surveys, because some employers may not keep such records of their employees or, if employers have such information, it may not be organized in a way that is easy to report for a survey. ${ }^{8}$

Establishment survey respondents typically provide more reliable information than household respondents do on some topics, such as the number of hours for which a worker is paid or the industry of the establishment. Information on the industry in which workers are employed is collected each month in the CPS. For broad industry categories, the CPS employment estimates generally are consistent with those obtained from establishment sources. For more detailed industry groups, however, CPS respondents may find it difficult to provide precise information on their employers' activities, products, or services. ${ }^{9}$

Establishments also furnish more reliable information than households do on the details of employer-provided benefit plans and the employers' costs for providing those benefits. Individuals may not have sufficient knowledge of their health or retirement plans to describe the types of plans or their provisions accurately. Response errors may be even more likely when proxy responses are allowed, as they are in the CPS. In the CPS, one person in a sampled household typically answers questions about himself or herself (self-responses) and everyone else in the household (proxy responses). Self-responses are thought to be more reliable than proxy responses, because people naturally can provide more precise information about themselves than about other people in the household, even if those others are close family members. ${ }^{10}$ A variety of presurvey testing procedures can help to identify and prevent problems that CPS respondents, whether providing self- or proxy responses, might have in answering questions. Even with such testing, however, the CPS often cannot provide information on benefit plans that is as precise as ebs data. The ebs is more likely to obtain accurate information about benefit plans be-

## Exhibit 1. Comparing the CPS and EBS: what information does each survey provide?

| Type of information | EBS | CPS | Which survey provides more reliable data? |
| :---: | :---: | :---: | :---: |
| General information |  |  |  |
| Demographic information | No | Yes | Only CPS provides |
| Industry information | Yes | Yes | Both have strengths ${ }^{1}$ |
| Occupational information | Yes | Yes | Both have strengths ${ }^{1}$ |
| Union membership | Yes | Yes | Each defines differently |
| Establishment size | Yes | Yes ${ }^{2}$ | EBS |
| Full- and part-time status .......................................................................... | Yes | Yes | Each defines differently |
| Health benefits |  |  |  |
| Participation in employer-provided plan ..................................................... | Yes | Yes | EBS |
| Employee eligibility, regardless of participation ............................................ | No | Yes ${ }^{3}$ | Only CPS provides |
| Health coverage from sources other than one's own employer ........................ | No | Yes ${ }^{4}$ | Only CPS provides |
| Employee premiums, deductibles, copayments, and coinsurance ...................... | Yes | No | Only EBS provides |
| Type of health plan (fee for service, PPO, HMO) .............................................. | Yes | No | Only EBS provides |
| Specific types of health services covered by plan .......................................... | Yes | No | Only EBS provides |
| Retirement benefits |  |  |  |
| Participation in employer-provided plan . | Yes | Yes | EBS |
| Employee eligibility, regardless of participation | No | Yes | Only CPS provides |
| Type of retirement plan (defined benefit or defined contribution) ..................... | Yes | Yes ${ }^{5}$ | EBS |
| Defined-benefit plan formula | Yes | No | Only EBS provides |
| Specific type of defined-contribution plan | Yes | Yes ${ }^{6}$ | EBS |
| Age and service requirements for normal- and early-retirement eligibility ......... | Yes | No | Only EBS provides |
| Eligibility and benefit levels for disability retirement | Yes | No | Only EBS provides |
| Employer contributions to defined-contribution plans | Yes | Yes ${ }^{5}$ | EBS |
| Coordination of defined-benefit plan payments with Social Security ................ | Yes | No | Only EBS provides |
| Vesting schedules | Yes | No | Only EBS provides |
| Survivor benefits | Yes | No | Only EBS provides |

${ }^{1}$ The eBS classifies industries and occupations somewhat more accurately, but because the CPS has a much larger sample size, it is able to provide more industry and occupational detail.
${ }^{2}$ The February 1995 and 1997 CPS supplements did not include any questions on establishment size or firm size. The CPS supplement conducted in May 1972 included questions on establishment size-that is, the number of people who work at the same location as respondents to the CPS sample work. The CPS supplements conducted in May 1979, 1983, and 1988 and April 1993 also included questions on establishment size. In addition, those supplements included questions on whether the employer operated at more than one location and, if so, how many people worked at all locations. Survey researchers have long considered responses to these questions to have poor accuracy, because many respondents to the CPS and other household surveys are unlikely to know how many people work for the employers of household members.
${ }^{3}$ The May 1988, April 1993, and February 1995 and 1997 CPS supplements included questions on eligibility to participate in employer-provided health plans, but the May 1979 and 1983 CPS supplements did not.
${ }^{4}$ The May 1988, April 1993, and February 1995 and 1997 CPS supplements included questions on health coverage from sources other than one's own employer, but the May 1979 and 1983 CPS supplements did not.
${ }^{5}$ The May 1988 and April 1993 CPS supplements included questions on the type of retirement plan and the employer's contribution to the plan, but the February 1995 and 1997 CPS supplements did not.
${ }^{6}$ The April 1993 CPS supplement included questions on specific types of defined-contribution plans, but the February 1995 and 1997 CPS supplements did not.
cause the data are obtained from plan brochures that establishments provide to BLS data collectors. ${ }^{11}$ (See exhibit 1 for a summary of the data provided by the CPS and EBS.) Estimates of health benefits coverage from both surveys are discussed next, followed by an examination of retirement coverage.

## Health benefits

CPS data on health insurance. The cPs employee benefits surveys, conducted in April 1972, May of 1979, 1983, and 1988, and April 1993, included questions on workers' health insurance coverage. No analysis of the health insurance data from the 1972 survey was published, and an electronic data file is no longer available for research, so trends that can be reviewed are those in health benefit coverage from 1979 forward. ${ }^{12}$ The May 1979 and 1983 CPS supplements simply asked respondents whether they were included in a health insurance plan on their present job. From that information, researchers calculated plan participation rates (also called coverage rates). By April 1993, the supplement had expanded to include questions on eligibility for insurance, insurance coverage from sources other than one's own employer, and reasons eligible employees did not participate in a health insurance plan offered by their employer. ${ }^{13}$

Information on health insurance coverage also was collected in the February 1995, 1997, and 1999 CPS supplements on workers in contingent and alternative work arrangements. Although employee benefits were not the primary subject of these supplements, questions on health and retirement benefits were included to provide information about the quality of jobs held by workers in all types of employment arrangements, including those in traditional arrangements, contingent or "temporary" arrangements, and alternative arrangements-such as independent contractors, employees of temporary help firms, and on-call workers. As mentioned previously, the employee benefits data from the February 1999 CPS are not yet available, so only data from the February 1995 and 1997 surveys will be examined.

Respondents to the foregoing February CPS supplementary questions were asked if employed members of their household had health insurance from any source. Respondents who replied affirmatively were asked if the employees received the health insurance from their own employer (including a tempo-rary-help agency or a contract company). If they did, they were asked if their employer paid for all, part, or none of the coverage. ${ }^{14}$ Those who reported that they did not receive coverage from their employer were asked to name the source of their health insurance. This question gave respondents a second chance to report coverage from their employer, as well as to report coverage from a spouse's or other family member's insurance, from other current or previous jobs, from medicare or medicaid, from insurance the worker purchased privately, or from some other source.

For workers who had no health insurance or who participated in a plan from a source other than their own employer, survey respondents were asked if the employer offered a plan and whether the worker was eligible to participate in it. If the worker had been eligible, the respondent was asked why the worker did not participate in the employer-sponsored plan.

Despite the different wording of questions between the CPS employee benefit supplements and the CPS contingent-worker supplements, the surveys found similar results. Two-thirds of wage and salary workers (public and private sector combined) had health insurance from their own employer in May 1979, 1983, and 1988. The proportion declined to 61 percent by April 1993. Rates of coverage computed using data from the February 1995 and 1997 CPs supplements were about the same-60 percent in both periods.

Full-time workers are much more likely than part-time workers to participate in an employer-provided health insurance plan. In February 1995 and 1997, about 70 percent of fulltime wage and salary workers were enrolled in a plan offered by their employer, compared with only 16 percent of part-time workers. The proportion of full-time workers participating in employer-provided health plans fell between 1979 and 1993 and was essentially unchanged after that. Rates of coverage for part-time workers changed little throughout the 1979-97 period, as the following tabulation of the percent of wage and salary workers participating in an employer-sponsored health plan shows:

|  | Total | Full time | Part time |
| :---: | :---: | :---: | :---: |
| $1979 \ldots \ldots \ldots \ldots .$. | 66 | 75 | 16 |
| $1983 \ldots \ldots \ldots .$. | 66 | 75 | 17 |
| $1988 \ldots \ldots \ldots \ldots$. | 65 | 74 | 15 |
| $1993 \ldots \ldots \ldots \ldots .$. | 61 | 71 | 16 |
| $1995 \ldots \ldots \ldots .$. | 60 | 70 | 16 |
| $1997 \ldots \ldots \ldots \ldots .$. | 60 | 70 | 16 |

Because the CPS collects information from employees rather than employers, it is possible to obtain information on health insurance that employees receive from sources other than their own employer, such as others' health plans. As shown in table 1, in February 1997, 79 percent of full-time, private-sector, nonagricultural wage and salary workers were eligible to receive health insurance from their employers. Another 15 percent were not eligible for coverage, and the remaining 7 percent did not provide information on eligibility. ${ }^{15}$ Eligibility rates were much lower for part-time workers: twenty-eight percent were eligible to participate in their employer's health plan in February 1997.

Of the 58.7 million full-time, private-sector, nonagricultural wage and salary workers who were eligible to receive health insurance coverage from their employer in February 1997, 84 percent elected to do so. Another 8 percent of eligible workers chose to receive coverage through a plan of a spouse or another family member. Less than 2 percent received coverage
from another source, such as an individually purchased plan. About 6 percent were not covered by any health insurance, despite being eligible to receive coverage from their employer. The primary reason reported for not being in the employer's plan was that it was too expensive.

Eleven million full-time, private-sector, nonagricultural wage and salary workers were not eligible to participate in their employer's health insurance plan. About 39 percent of these workers participated in a health plan from some other source. The remaining 61 percent, 6.7 million workers, had no health insurance coverage at all. (See table 1.)

The February 1997 CPS supplement found that, among fulltime, private-sector, nonagricultural wage and salary workers, employed men and women were about equally likely to be eligible for employer-provided health insurance. As shown in table 1 , just under 8 in 10 in each group had the option of such coverage at the time of the survey. Among those who were eligible, men were more likely than women to accept coverage from their employers- 87 percent compared with 80 percent. Women were more likely than men to be covered by their spouse's or another family member's insurance. Among workers who were not eligible for health insurance from their employers, men were more likely than women to have no coverage at all. (See table 1.)

Health insurance eligibility and coverage increase with age.

In February 1997, about 45 percent of full-time, private-sector, nonagricultural wage and salary workers aged 16 to 19 were eligible for coverage from their employers, and a quarter of teens employed full time actually participated in their employers' health plan. (Table 2 provides information on plan participation, but not on eligibility.) Eligibility increased to 65 percent for those aged 20 to 24 , and half of the group participated. Eight in 10 workers aged 25 and older were eligible for, and 7 in 10 participated in, employer-provided plans. Rates were somewhat lower for persons aged 65 and older, but nearly all persons in this group receive hospital and medical insurance through medicare, regardless of whether they are employed. ${ }^{16}$

EBS estimates of employer-provided health insurance. According to the EBS, medical care benefits are provided to almost threefourths of the full-time civilian workers in the private sector and State and local governments. Participation rates are higher among State and local government workers ( 87 percent) than those in the private sector ( 71 percent). Within the private sector, employees of medium and large establishments are more likely to participate in a health insurance plan ( 77 percent) than are those working in small establishments ( 66 percent).

Table 1. cps estimates of health coverage for full-time, private-sector, nonagricultural wage and salary workers, by source of coverage, February 1997
[Numbers in thousands]

insurance participation among full-time, private-sector, nonagricultural workers are 3 to 8 percentage points higher than estimates derived from the cPs. As shown in table 3, this is true regardless of whether workers are in a union, are employed in goods-producing or service-producing industries, or are in white-collar, blue-collar, or service occupations. ${ }^{17}$ Among State and local government employees, the pattern holds for nonunion workers, with the EBS showing 86 -percent participation and the CPS 83 percent. Among government workers in unions, however, the CPS estimate of 93 percent was higher than the ebs estimate of 87 percent. One reason for the generally higher rates from the EBS may be the inclusion in the EBS participation measure of workers who have not yet satisfied their employers' length-of-service requirements needed prior to enrolling in their health insurance plan. In the cPS, such workers may not describe themselves as being covered by an employer-provided health plan.

Industry and occupation. The ebs and cPs both provide information on participation in employee benefit plans by industry

and occupation. Because the size of the cPs sample is considerably larger than that of the EBS, researchers using the CPS can calculate estimates for more detailed industries and occupations than is possible by using the ebs. ${ }^{18}$

CPS estimates in table 4 show that participation in an em-ployer-provided health plan was much more common among full-time State and local government employees ( 88 percent) than among private-sector employees ( 66 percent). Within the major industry categories in the private sector, workers in mining and manufacturing were the most likely to participate in an employer-provided health plan, with at least 8 in 10 em ployees enrolled. High coverage in communications and public utilities (86 percent) drove up the overall rate for the transportation and public utilities industry. Workers in agriculture (34 percent), construction (43 percent), and retail trade (49 percent) were the least likely to participate in an employerprovided health plan. Within retail trade, the participation rate for full-time workers in eating and drinking places, at 28 percent, was especially low. By comparison, 57 percent of fulltime workers in other retail industries received health insurance from their employer.

In virtually every industry shown in the table, workers in unions had higher coverage rates than nonunion workers. As indicated in the following tabulation, EBS estimates show that union workers have higher participation rates in employerprovided health insurance plans than nonunion workers have, both in medium and large establishments and in small establishments (the union-nonunion difference in participation rates, however, is greater in small establishments): ${ }^{19}$

| Percent |  |
| :---: | :---: |
| Union | Nonunion |
| 85 | 74 |
| 94 | 64 |

Table 5 shows health plan participation rates estimated from the CPS for full-time, private-sector, nonagricultural workers, by occupation. Eight in 10 professionals and nearly as many managers were covered by employer-provided health insurance in 1997. Coverage was also relatively high among technicians ( 73 percent) and workers in administrative support occupations ( 69 percent). About two-thirds of persons employed in precision production and operator occupations were covered. Participation was lowest in service occupations ( 40 percent) and in farming and related jobs ( 35 percent).

Detailed provisions of health plans. Establishments responding to the EBS are asked to provide brochures that describe the detailed provisions of their employee benefit plans. EBS data
on these plans and their provisions are available from a variety of bls publications. ${ }^{20}$ It would be nearly impossible to collect this type of information in the CPS, because most respondents would not know the answers to many of the specific questions on the details of their plans, and they would be unlikely to have brochures to provide to CPS interviewers.

Health care plans offered by employers can be categorized into three types, based on the method of selecting medical service providers and paying for care: traditional fee-for-service plans, preferred provider organizations (PPO's), and health maintenance organizations (HMO's). Despite the growth in alternative health plans, the traditional fee-for-service plan remains the most common. About 33 percent of full-time workers in 1994-95 participated in a fee-for-service plan, compared with 22 percent in a PPO and 18 percent in an нмо. Table 6 shows the distribution of types of plans, by major industry and occupation group. (See box, p. 10, for a more detailed description of the three types of health care plans.)

The ebs also provides information on the percentage of work-
ers covered by dental, vision, and prescription drug benefits. As the following tabulation shows, nearly half of full-time civilian employees in 1994-95 received dental care benefits from their employer, one-fifth received vision care benefits, and 70 percent received prescription drug benefits:

|  | Percent |  |  |  |
| :--- | :---: | :---: | :---: | :---: |
|  | Medical Dental Vision | Drug |  |  |
| Total, all civilian workers ... <br> Private: <br> Medium and large | 73 | 45 | 20 | 70 |
| establishments ............. | 77 | 57 | 24 | 74 |
| Small establishments ..... | 66 | 28 | 10 | 60 |
| State and local <br> government .................. | 87 | 62 | 35 | 86 |

The extent of coverage differed in each of the three Employee Benefits Surveys (of medium and large establishments, small establishments, and State and local government), but, regardless of which survey is considered, prescription drug coverage is the most common benefit and vision care the least common.

The following are other types of EBS information that are published regularly:

- the kinds of specific medical, surgical, psychiatric, and dental procedures the plan will cover;
- the amount of any premiums, deductibles, copayments, or coinsurance that plan participants must pay;
- the maximum out-of-pocket expenses that plan partici-
pants may incur for procedures;
- the maximum lifetime benefits the plan will pay for a participant's medical expenses;
- the procedures that plan participants must follow to obtain second surgical opinions, reimbursement for emergency treatment, and so forth.

When the bls National Compensation Survey is fully developed, the sample design, data collection, and processing procedures used to estimate participation in employee benefit plans will be linked to measures of employer costs for benefits. These cost measures currently are published by the Bureau of Labor Statistics in the series titled "Employer Costs for Employee Compensation." Employer costs for health benefits accounted for 21 percent of the cost of benefits for civilian workers in 1999. ${ }^{21}$

## Retirement benefits

CPS data on retirement benefits. The CPS questions on participation in retirement plans changed at least slightly each year they were asked during the 1972-93 period, complicating historical comparisons of the estimates. Despite these changes, the proportion of full-time wage and salary workers in the private sector who participated in employer-sponsored retirement plans remained within a narrow range around 50 percent during the 1972-93 period.

The April 1993 CPS included two questions designed primarily to determine whether an employee participated in an

## Types of health care plans measured in the Employee Benefits Survey

Fee-for-service plans allow patients to choose their own health care providers. The plan reimburses the worker or health care provider after services are received. Benefits are typically subject to major medical limitations, including deductibles, coinsurance, out-of-pocket expense limits, and maximum allowances.

In a preferred provider organization (PPO), participants are covered for medical services at a higher rate of reimbursement if they receive care from designated hospitals, physicians, laboratories, or dentists. Individuals may also choose their own provider, although usually at a lower rate
of reimbursement. As in fee-for-service plans, with PPO's, benefits are typically subject to limitations, including deductibles, coinsurance, out-of-pocket expense limits, and maximum allowances that apply to many or all services.

Health maintenance organizations (HMO's) provide a fixed set of medical benefits for a prepaid fee. Most medical services either are covered in full or require patients to pay a nominal copayment, but generally restrict enrollees to specific providers. There are two types of нмо: group/staff arrangements, with services provided in central facilities, and individual practice associations, with providers working from their own offices.
employer-provided retirement plan:

1. Now I'd like to ask about retirement benefits on your job-not government programs like Social Security, but employer-sponsored plans. This includes regular pensions. It also includes other plans where money is accumulated in an individual account for retirementlike thrift, savings, profit-sharing, or stock plans. First, does your employer or union have any such pension or retirement plan for anyone in your company or organization?

| Yes | (Go to 2.) |  |
| :--- | :--- | :--- |
| No | (Go |  |
| Don't know | $\bigcirc$ |  |

2. Are you included in such a plan?

| Yes | 0 |
| :--- | :--- |
| No | 0 |
| Don't know | 0 |

Persons who responded affirmatively to both questions are counted as participating in an employer-provided retirement plan. Persons who did not say "yes" to both questions still could be counted as having retirement coverage if they responded affirmatively to the following question, asked later in the supplement about participation in a tax-deferred retirement plan:

Some retirement plans allow workers to make tax-deferred contributions to the plan. For example, you might choose to have your employer put part of your salary into a retirement account, and then you don't pay income taxes on this money until you take it out or retire. These plans are called by different names, including $401(\mathrm{k})$ plans, pre-tax plans, salary reduction plans, and 403(b) plans. Do you participate in a plan like this?

It is not clear why some respondents would answer "no" to either of the two main questions on retirement coverage and subsequently answer "yes" to the question on participation in a tax-deferred retirement plan. Nevertheless, some respondents did, and they are counted as participating in an employer-provided retirement plan. ${ }^{22}$ The May 1983 and 1988 supplements included similar questions on participation in tax-deferred retirement plans. The May 1979 supplement did not include such a question, because tax-deferred retirement plans were a new phenomenon at that time, just having been permitted under Federal law with the passage of the Revenue Act of 1978.

In the February 1995 and 1997 CPS supplements on workers in contingent and alternative work arrangements, the two main questions on retirement benefits were similar, although considerably more brief, than those asked in the April 1993 supplement:

1. Does (fill in employer's name) offer a pension or retirement plan to any of its employees?

$$
\begin{array}{lll}
\text { Yes } & 0 & \text { (Go to } 2 .) \\
\text { No } & 0 &
\end{array}
$$

2. Are you included in this plan?

> Yes
> No

An affirmative response to both questions resulted in the worker being counted as participating in an employer-sponsored retirement plan. The February cps supplements did not include any follow-up questions specifically about participation in tax-deferred retirement plans. Despite the seemingly substantial differences in the questions asked in 1995 and 1997

compared with those asked in 1993, there was little difference in the estimated proportion of employed private, nonagricultural wage and salary workers participating in employer-provided retirement plans, as shown in the following tabulation:

|  | Percent |  |  |
| :---: | :---: | :---: | :---: |
|  | 1993 | 1995 | 1997 |
| Total employed ................. | 44 | 42 | 43 |
| Full time.................... | 51 | 49 | 50 |
| Part time.............................. | 13 | 12 | 13 |

EBS data on retirement plans. Information gathered from employers in the 1994-95 EBS shows that 66 percent of all full-time workers in private industry and State and local government participate in employer-sponsored retirement plans. Participation among government workers is higher ( 95 percent) than those in
private industry ( 60 percent).

CPS and EBS estimates of retirement plan coverage. cPs estimates of participation in retirement plans are considerably lower thań estimates derived from the ebs. Among full-time workers, the gap in estimates between the two surveys is 10 or more percentage points, regardless of whether the workers are union or nonunion, in goods-producing or service-producing industries, or in white-collar, blue-collar, or service occupations. (See table 7.) Furthermore, the gap in retirement coverage between the surveys is larger than that found for health coverage.

There also are large differences between the surveys in the estimated retirement plan participation rates for workers in State and local governments. According to the CPS, 86 percent of full-time State and local government employees participated in an employer-provided retirement plan in 1995, and 87 per-

NOTE: Dash indicates data are not available.
Source: Current Population Survey, February 1995 and 1997; Employee Benefits Survey, 1994 and 1995.
cent participated in 1997. By comparison, the participation rate estimated from the 1994 ebs was 95 percent. Among unionized workers, however, there was essentially no difference: both the CPS and the ebs show that about 93 percent of unionized State and local government employees participated in a retirement plan. Among nonunion public-sector workers, 82 percent participated in a plan according to the CPS, compared with 96 percent according to the EBS.

It is difficult to explain why the CPS estimates of retirement plan coverage systematically tend to be lower than those derived from the EBS. It also is not clear why the gap between the surveys is larger for retirement benefits than for health benefits. If one assumes that the EBS estimates are closer to the true coverage rates that exist in the workforce, then it may be that the underestimates from the CPS result from some respondents' lack of knowledge about their own benefits coverage or the benefits coverage of other household residents for whom they responded. More respondents may be able to answer questions correctly about health coverage than about retirement coverage because health benefits presumably are used more frequently by a larger number of CPS respondents. Unless a worker expects to retire in the fairly near future and thus may think about or discuss retirement issues frequently, many CPS respondents may know little, if anything, about the worker's participation in an employer-provided retirement plan. Furthermore, as with health care, the EBS participation measure includes workers who have not yet satisfied their employer's length-of-service requirement for participation in the retirement plan. These reasons for the gap in estimates between the CPS and EBS are speculative, but regardless of the reason, researchers, policymakers, and other users of the data should be aware that the estimated coverage rates from the eBs are considerably higher than those from the CPS.

Demographic data on retirement coverage. As shown in table 8 , retirement plan participation rates estimated from the CPS are low for full-time, private-sector, nonagricultural wage and salary workers aged 16 to 19 and 20 to 24. Participation rates then rise with age for men and women, until peaking at 60 percent among workers aged 45 to 54 and 55 to 64 . Full-time workers aged 65 and older are only about two-thirds as likely as 45 - to 54 -year-olds and 55 - to 64 -year-olds to participate in a retirement plan. Overall, men are slightly more likely than women to participate in a plan, although the gap has narrowed considerably since the early 1970s, as the participation rate for men edged down slightly while the rate for women rose by 10 percentage points. The gap between men's and women's retirement plan participation rates is considerably larger among workers aged 45 and older than it is among workers in younger age groups. Whites are slightly more likely than blacks to participate in a retirement plan, and both groups are considerably more likely than Hispanics to participate.

Industry and occupation. The cPs data in table 9 show that fulltime workers in manufacturing and in finance, insurance, and real estate had the highest retirement plan participation rate (62 percent) among the major private, nonagricultural industries in 1997. The participation rate for workers in transportation and public utilities ( 61 percent) was also high, although there was a sizable gap in rates between full-time workers in transportation (49 percent) and those in communications and public utilities (77 percent). Full-time workers in retail trade ( 31 percent) and construction ( 29 percent) had the lowest retirement plan participation rates in the private, nonagricultural sector. Workers in those industries were about 3 times as likely as agricultural workers were to participate in a plan. Full-time workers in government were considerably more likely than those in the
private sector to participate in a retirement plan. The rate for Federal employees was 88 percent in 1997, while 87 percent of State and local government workers participated in a retirement plan. ${ }^{23}$

Table 10 shows retirement plan participation rates estimated from the CPS for full-time, private-sector, nonagricultural workers, by occupation. Sixty-five percent of workers in professional specialty occupations participated in a retirement plan, as did 60 percent of workers in executive, administrative, and managerial occupations. Fifty-nine percent of technicians and related support workers and 54 percent of administrative support workers (including clerical workers) participated in a plan. Just under half of full-time sales workers; operators, fabricators, and laborers; and precision production, craft, and repair workers participated in a plan. Less than a quarter of workers in service occupations had retirement plan coverage.

Characteristics of retirement plans. In addition to the questions used to determine whether workers participated in retirement plans, the May 1988 and April 1993 cps supplements included questions about the characteristics of those plans. ${ }^{24}$

[^5]One key feature of retirement plans is the type of plan. Broadly speaking, there are two types of retirement plans: defined-benefit and defined-contribution plans. Defined-benefit plans legally obligate employers to pay retirees an annuity that is based on a specified formula. The size of the benefit usually depends on the retiree's preretirement salary and number of years of service with the employer. The employer is responsible for making contributions to the pension fund, investing the fund's assets, and paying benefits. The employer also bears the risk if investments perform poorly.

Defined-contribution plans typically specify how much an
employer has agreed to contribute to each employed participant's individual account, but do not stipulate the amount of benefits that will be paid during retirement. ${ }^{25}$ Many defined-contribution plans also permit employees to contribute to their accounts, often on a tax-deferred basis. The size of the benefit each participant receives during retirement depends on the amount the employer and employee contributed to the plan and the investment earnings on the contributions. There are several types of defined-contribution plans, including tax-deferred 401(k), 403(b), and Section 457 plans, which are named after the sections of the U.S. Internal Revenue Code that permit them to be established. Other types of defined-contribution plans include deferred profit-sharing plans, money purchase pension plans, employee stock ownership plans, and stock bonus plans.

EBS estimates of retirement plan coverage show that 42 percent of full-time workers are covered by a defined-benefit plan, compared with 39 percent by a defined-contribution plan. Fifteen percent participate in both types of plans. Nearly all State and local government workers with retirement coverage participate in a defined-benefit plan. Unionized workers in the private sector are much more likely to participate in a defined-benefit plan than in a defined-contribution plan. (See table 11.)

There is some doubt concerning whether respondents to household surveys such as the CPS are able to provide information on the types of retirement plans they participate in as accurately as respondents to establishment surveys. A look at the data suggests that CPS responses in this regard are not without problems. In the April 1993 cPS, 53 percent of private-sector retirement plan participants (full and part time combined) reported that they were participating in a defined-benefit plan, 46 percent responded that they were in an "individual account" or definedcontribution plan, 7 percent said that they participated in some "other" type of plan, and 12 percent did not know the type of plan they were in. (The sum of these percentages is greater than 100, because some workers participate in more than one type of plan.) By comparison, estimates from the eBs show that 55 percent of private-sector retirement plan participants in 1994-95 were in a defined-benefit plan, a figure similar to the 53 percent estimated from the April 1993 cPs. For defined-contribution plans, however, estimates from the two surveys differ widely. According to the EBS, 73 percent of private-sector retirement plan participants were in a defined-contribution plan, a considerably higher proportion than the CPS estimate ( 46 percent).

The large discrepancy in the estimated proportions participating in defined-contribution retirement plans signals one problem with the CPS responses, but there also are several other problems. First, under Internal Revenue Service regulations, all retirement plans are either defined-benefit or defined-contribution plans; there is no "other" plan type. The implausible "other" responses, along with the proportion of participants who did not know the type of plan they were in, compose nearly a fifth of the cPS respondents who participated in em-ployer-provided retirement plans in April 1993. These prob-
lems raise doubts about the reliability of cPs information on the types of retirement plans in which workers participate. Some CPs respondents may not have sufficient knowledge of employee benefit plans and terminology to provide detailed information about their provisions. And the problem may be more acute with proxy responses.

Using brochures obtained from establishments, the EBS ascertains a variety of details about retirement plans. This information is nearly impossible to obtain in the CPS. EBS data on the details of these plans are available from a variety of BLS publications. ${ }^{26}$ Among such details are the following:

- age and service eligibility requirements for retirement
- formulas used to determine the payments retirees receive from defined-benefit plans
- how defined-benefit plan payments are coordinated with Social Security payments
- eligibility and benefit levels for disability retirement
- payments to survivors after the employee's or retiree's death
- increases in postretirement benefits
- specific types of defined-contribution plans, such as savings and thrift, deferred profit-sharing, or stock plans
- methods used to determine the amount of employer contributions to defined-contribution plans
- vesting schedules that determine how much employees can receive from defined-benefit or defined-contribution plans if they leave the employer before retirement

As described earlier, the bls National Compensation Survey that is currently being developed will link information on plan participation and characteristics with data on employer costs. Such cost information currently is provided in the series on Employer Costs for Employee Compensation. ${ }^{27}$

Tax-deferred retirement plans. Despite the problems with the CPS data on participation in defined-benefit and defined-contribution retirement plans, the questions in the April 1993 supplement that asked specifically about participation in taxdeferred retirement plans may provide useful information. Respondents may know more about these tax-deferred plans because, unlike determining their participation in many other types of retirement plans, workers must actively choose whether to participate in tax-deferred retirement plans and how much to contribute to them. Workers who participate in such plans also frequently are reminded of their participation because their pay stubs may indicate the amount deducted from their pay and invested in the tax-deferred plan. Many plan participants also receive monthly, quarterly, or annual financial statements that indicate how much money is in their account, as well as the amount of contributions and investment performance since the previous statement. The first four CPS questions on taxdeferred retirement plans read as follows (the first question
was presented earlier in this article):

1. Some retirement plans allow workers to make tax-deferred contributions to the plan. For example, you might choose to have your employer put part of your salary into a retirement account, and then you don't pay income taxes on this money until you take it out or retire. These plans are called by different names, including $401(\mathrm{k})$ plans, pre-tax plans, salary reduction plans, and 403(b) plans. Do you participate in a plan like this?

| Yes | 0 | (Go to 3.) |
| :--- | :--- | :--- |
| No | 0 | (Go to 2.) |
| Don't know | 0 |  |

2. Does your employer offer you a plan like this?

| Yes | (Go to 4.) |  |
| :--- | :---: | :---: |
| No | (G) |  |
| Don't know | 0 |  |

3. Approximately what percent of your gross pay will you contribute to the plan this year?

|  |  |  |
| :--- | :--- | :--- |
| Don't know | 0 | (Go to 4.) |
| Refused | $\bigcirc$ |  |

4. If you were to contribute $\$ 100$ to this plan, how much would your employer contribute?

$$
\$
$$

Nothing

Would contribute something, but don't know how much
Contribution rate varies
Don't know

The first question provides information on the number of workers who participate in tax-deferred retirement plans. As table 12 shows, 28 percent of full-time, private-sector, nonagricultural wage and salary workers participated in a tax-deferred retirement plan in April 1993, according to the CPS. The comparable eBS estimate for 1994-95 is 38 percent. As with the estimates on participation in all types of retirement plans, the CPS estimate for participation in tax-deferred plans is considerably lower than the EBS estimate. Again, it is not clear why this difference occurs, although one could speculate that employers are better able to provide accurate information on participation in retirement plans than are workers or their proxy respondents.

In conjunction with the first CPS question on tax-deferred retirement plans, the second question provides information on the number of workers who are eligible to participate in a
plan, regardless of whether they actually contribute to it. Together, these two questions can be used to determine the proportion of eligible workers who choose to contribute to a plan. The ebs, by comparison, does not provide a direct measure of workers who are eligible to participate. ${ }^{28}$ According to the CPS, 40 percent of full-time, private-sector, nonagricultural wage and salary workers were eligible to participate in a taxdeferred retirement plan in April 1993, and of those eligible, 68 percent actually chose to contribute to the plan. Readers should keep in mind that the CPS estimate of eligible workers may have its flaws, because some respondents-especially proxies - may not be aware that a worker is eligible for a plan if he or she does not actually contribute to it. Thus, the CPS may understate eligibility even more than it appears to understate participation. Nevertheless, it is useful for employers, public policymakers, and others to have some measure of how many workers who were offered a tax-deferred retirement plan take advantage of the opportunity to invest in it.

The third CPS question on tax-deferred retirement plans provides information on the percentage of pay that participants contributed to the plan. Among full-time participants in April 1993, only 73 percent responded with the percentage of their pay that they contributed to the plan; the remaining 27 percent either did not know the percentage or did not respond. There is no way to verify the accuracy of the responses of participants who did respond with a percentage, but some undoubtedly are inaccurate, especially when obtained from proxies. The ebs used to include a question on the average percentage of pay that all participants in an establishment contributed to their tax-deferred retirement plan. As with the cPS question, the nonresponse rate was high, and many of the responses that employers provided may not have been accurate. Apparently, many employers did not have the information organized in a way that would enable them to provide an accurate response easily. Because of these problems, the question was eliminated from the ebs.

The fourth CPS question on tax-deferred retirement plans asks whether employers supplement employee contributions and, if so, the amount of the employer contribution. As shown in table 12, 68 percent of full-time plan participants received a contribution from their employer, according to the April 1993 CPS. The estimate from the 1994-95 EBS, by comparison, was 85 percent. Many CPS respondents may not be familiar with the details concerning contributions to a plan from their employers, whereas the documentation that establishments provide to EBS data collectors usually describes in detail whether and how much the employer contributes to a plan. This disparity suggests that the EBS information on employer contributions is more accurate than that of the CPS.

## Linked surveys

It is clearly beneficial for researchers, policymakers, and others to have information on the relationship between participa-

tion in employee benefit plans and the sex, age, race, marital status, and other demographic characteristics of workers. Demographic information is best obtained from household surveys like the CPS. As the previous sections have shown, however, the CPS is not as well suited as the EBS to provide accurate information on employee benefits. Accordingly, rather than asking household respondents to provide information on employee benefits and asking employers to provide demographic information, it may be preferable to ask each source for the information that they can provide more accurately. Some researchers have taken such an approach and developed data sources that combine information obtained from both employers and their workers. The development of these linked em-ployer-employee data sets has increased in the United States in recent years, although some other industrialized countries are more advanced than the United States in that regard. Indeed, a May 1998 conference on linked employer-employee data, held in Washington, dc, attracted social scientists and statisticians from more than 20 countries. ${ }^{29}$

Linked employer-employee data sets take a variety of forms. Some involve linking existing household survey data with existing administrative or survey data from establishments. Other data sets have been designed specifically to collect information from employers as well as employees. The
administrators of such surveys may sample and gather information from establishments and subsequently ask questions of a sample of employees within those establishments. The 1995 bLS Survey of Employer-Provided Training (SEPT95) was designed in this way. ${ }^{30}$ A 1993 survey sponsored by the W.E. Upjohn Institute for Employment Research used the same approach to obtain information from employers and workers regarding on-the-job training, wages, schooling, experience, and employee benefits. ${ }^{31}$

An alternative approach to designing linked surveys is to sample households and ask the individuals in them to provide information about themselves, along with the names, addresses, and telephone numbers of their employers. With the consent of the employees, data collectors then contact the employers and gather additional information from them. The bLs National Longitudinal Surveys (NLS) have used this approach in a number of instances. Recently, information on participation in re-

'The Current Population Survey estimate of the number of participants in tax-deferred retirement plans who received no employer contributions includes participants who explicitly said their accounts received no employer contributions, as well as those who refused to answer or did not know whether the employer contributed.

Note: Medium and large establishments are those with 100 or more workers. Small establishments have fewer than 100 workers.

Source: Employee Benefits Survey, 1994 and 1995; Current Population Survey, April 1993.
tirement plans was collected from respondents to the NLS Mature Women's survey, and detailed information about the plans was subsequently obtained from employers. ${ }^{32}$

Linked employer-employee data sets have two primary objectives. One objective is to compare how employers and employees respond to the same questions, thereby providing researchers with insight on the accuracy of responses to their surveys. A 1983 study, for example, examined two different linked data sets that included information from employers and their workers on the employers' industries, the workers' occupations, coverage under a union contract, weekly hours worked, and wages. ${ }^{33}$

Another, more common, objective of linked data sets is to obtain the kinds of information from employers and employees that each can provide more easily and accurately. Ideally, the resulting data set could afford more accurate information without having to ask household or establishment respondents questions that they are not well equipped to answer. In addition to improving accuracy and reducing the burden on re-spondents-by asking individuals and establishments only those questions they can most easily and accurately answerlinked data sets also provide researchers and policymakers with insights into the interactions between employers and workers. Information on these interactions can be useful for investigating a variety of research questions, such as how employers and workers negotiate pay rates. ${ }^{34}$ Employer-employee interactions cannot be measured using traditional household or establishment data sources alone.

Linked data sets have their advantages over traditional household and establishment information sources, but they also
have their problems. For example, successfully linking existing household and establishment data requires having sufficient information to identify employers from the one survey with household members from the other, but such identifying information is not always available or complete. Moreover, surveys designed specifically to collect information from employers and their workers typically cost more to administer than traditional surveys, because employers and employees both must be contacted. Accordingly, response rates often are lower, because the need to contact both kinds of respondents increases the probability that sampled establishments or individuals may be unable or unwilling to respond. ${ }^{35}$ Also, as with traditional surveys, linked surveys present concerns about the privacy of participants and the confidentiality of their responses. And such concerns are heightened in linked surveys because, for instance, employees may feel uncomfortable about having their employers contacted, and employers likewise may not want their employees to be contacted.

This article has identified some of the difficulties that are inherent in collecting detailed information on health and retirement benefits in the household-based Current Population Survey. The establishment-based Employee Benefits Survey provides more accurate information on employee benefits, but it is not well suited to providing information on workers' demographic characteristics or, for example, health insurance that they receive from sources other than their own employers. If the difficulties with linked surveys regarding cost, response rates, and confidentiality can be resolved, such a survey design may enable researchers to
combine the best attributes of household and establishment data sources to obtain more accurate and useful information
on employee benefits. No such linkage is planned by the Bureau of Labor Statistics at this time, however.

## Notes

For a more complete discussion of the elements of job quality, including employee benefits, see Joseph R. Meisenheimer II, "The services industry in the 'good' versus 'bad' jobs debate," Monthly Labor Review, February 1998, pp. 22-47.
${ }^{2}$ Employer Costs for Employee Compensation-March 1999, USDL 99173 (U.S. Department of Labor, June 24, 1999).

See, for example, Sylvester Schieber and John Shoven, eds. Public Policy Toward Pensions (Cambridge, MA, mrt Press, 1997).
${ }^{4}$ The importance of having accurate information to develop public policy on health care is discussed by Linda T. Bilheimer and Robert D. Reischauer in "Confessions of the estimators: Numbers and health reform," Health Affairs, Spring 1995, pp. 37-55.
${ }^{5}$ For more information on the National Compensation Survey, see Harriet G. Weinstein, "Overview of the ncs: Summer 1998," Compensation and Working Conditions, Summer 1998, pp. 41-44.
${ }^{6}$ All of these supplements included questions on employer-provided health and retirement benefits. The May 1988 and April 1993 supplements also included questions on short- and long-term disability benefits, which are not analyzed in this article.
${ }^{7}$ The March supplement to the CPS has included questions on health insurance coverage since 1980. These questions focus on coverage from all sources and have provided less reliable information than the supplements on employer-provided health insurance benefits. See Mark C. Berger, Dan A. Black, and Frank A. Scott, "How Well Do We Measure Employer-Provided Health Insurance Coverage?" Contemporary Economic Policy, July 1998, pp. 356-67.
${ }^{8}$ Information on educational levels also appears to be more easily obtained from household surveys than from establishment sources. Information on educational attainment is available each month from the CPS, and estimates are published in the monthly news release, The Employment Situation, and in the blS publication, Employment and Earnings.

BLs recently asked employers in four metropolitan areas to provide information on educational attainment in test studies of the National Compensation Survey. These tests showed that employers were unable to provide information on educational attainment for 7 in 10 workers. Although it may surprise some readers that employers so often were unable to provide information about the educational attainment of their workers, it is important to remember that employers may not always find such information relevant. For example, many service and laborer occupations do not require academic credentials to perform the job adequately. Even in specialized trades like plumbing and carpentry, work experience in the occupation is far more relevant to employers than is educational attainment. See John E. Buckley, "Collecting Data on Human Capital Variables," Compensation and Working Conditions, Fall 1998, pp. 29-31.
${ }^{9}$ In addition to the employment estimates from the CPS, employment estimates also are available from the bLs Current Employment Statistics (CES) program, a monthly survey of nonfarm establishments that obtains information on employment, hours, and earnings by industry. To illustrate the differences that can occur between CPS and CES employment estimates for detailed industries, consider the personnel supply services industry, which consists largely of firms that provide temporary employees to establishments in other industries. The 1998 annual average employment level estimated from the CPS for this industry was about 1 million. The employment estimate from the CES program was 3.2 million. In part, this large discrepancy stems from the different treatment of multiple jobholders in each survey. Persons who are paid by more than one "temporary-help" or "staffing" firm during a survey reference period are counted only once in the CPS; in the CES program, these
individuals are counted in the employment records of each staffing firm for which they worked. A larger part of the discrepancy probably results from the different way in which the industry is reported in the two surveys. Many CPS respondents may report the industry of the client to which a temporary worker was assigned, rather than that of the staffing firm which provided the worker to the client. By comparison, respondents to the ces program report the industry of the establishment that pays the worker-that is, the staffing firm. Thus, if one wants to know how many people are employed in the personnel supply services industry, establishment data are a more reliable source of information than the CPS.
${ }^{10}$ This does not, of course, imply that proxy responses are always unreliable. In fact, for many important items in the cPS, such as a person's employment or unemployment status, proxy responses may be as reliable as self-responses, at least when an adult respondent answers questions about the labor force activity of another adult in the household. Assessing the accuracy of a response is more ambiguous when the response is from an adult who is answering questions about the labor force activity of youths in the household. For a more detailed discussion of proxy responses in the CPS, see Brian A. Kojetin and Judith M. Tanur, "Proxies for Youths and Adults: Communication and Reports of Job Search," 1996 Proceedings of the Section on Survey Research Methods, vol. 1 (Alexandria, va, American Statistical Association, 1997), pp. 254-59. See also Norman Bowers, "Youth labor force activity: alternative surveys compared," Monthly Labor Review, March 1981, pp. 3-17. Without proxy responses, the CPS would cost far more to administer because CPS interviewers typically would have to contact sampled households several times to obtain information from each resident of the household. The only alternative to using proxy responses or incurring higher costs would be to obtain no information at all for some household residents.
${ }^{11}$ In addition to health insurance and retirement plan provisions, the EBS compiles data on employee work schedules, paid leave, disability benefits, life insurance, flexible benefits plans, and reimbursement accounts, as well as a variety of emerging benefits.
${ }^{12}$ The April 1972 CPS supplement was a mail survey that examined the benefits coverage of full-time workers. Data on retirement benefits were examined in Walter W. Kolodrubetz and Donald M. Landay, "Coverage and Vesting of Full-Time Employees Under Private Retirement Plans," Social Security Bulletin, November 1973. Health benefits data from the April 1972 CPS supplement were not analyzed in that article.
${ }^{13}$ Retirement plan coverage rates from 1972 to 1993 were published in Pension and Health Benefits of American Workers: New Findings from the April 1993 Current Population Survey (U.S. Department of Labor, Social Security Administration, Small Business Administration, and Pension Benefit Guaranty Corporation, 1994).
${ }^{14}$ The EBS measures, among other things, employee benefit programs sponsored by employers who pay some share of the costs.
${ }^{15}$ The high nonresponse rate on this question partly reflects some proxy respondents' lack of knowledge about health plan options of other household members.
${ }^{16}$ Databook on Employee Benefits, 4th ed. (Washington, DC, Employee Benefit Research Institute, 1997), p. 301.
${ }_{17}^{17}$ The eBS and the CPS define union membership differently. In the EBS, the establishment identifies the number of workers in union occupations. Those occupations fulfill the following requirements: a labor organization must be recognized as the bargaining agent for all workers in the occupation; wage and salary rates are determined through collective bargaining and negotiations; and settlement terms, which must include earnings provisions and may include benefit provisions, are embodied in a signed,
mutually binding collective bargaining agreement. In the CPS, union members are respondents who replied affirmatively to the question, "On this job, (is/are) (name/you) a member of a labor union or of an employee association similar to a union?"
${ }^{18}$ The cPS sample currently includes 50,000 households each month. The 1995 Employee Benefits Survey of Medium and Large Private Establishments sampled 3,462 nonagricultural establishments with 100 or more workers. The 1994 Employee Benefits Survey of Small Private Establishments sampled 2,135 nonagricultural establishments with fewer than 100 employees. The 1994 Employee Benefits Survey of State and Local Governments sampled 860 government establishments.
${ }^{19}$ An establishment is an economic unit-such as a factory, a mine, a store, or an office-that produces goods or provides services, typically in a single physical location. An establishment is distinct from a firm, which may be in a single physical location or may include multiple establishments at different locations. The eBS samples are drawn from a list of establishments, not firms, and readers should be aware that some participants in the survey of small establishments may in fact be a part of large firms.
${ }^{20}$ See, for example, Employee Benefits in Medium and Large Private Establishments, 1995, Bulletin 2496 (Bureau of Labor Statistics, April 1998); Employee Benefits in Small Private Establishments, 1994, Bulletin 2475 (Bureau of Labor Statistics, April 1996); and Employee Benefits in State and Local Governments, 1994, Bulletin 2477 (Bureau of Labor Statistics, May 1996).
${ }^{21}$ The Employer Costs for Employee Compensation series provides estimates by industry and major occupational group, as well as by bargaining status, region, and establishment size. Not surprisingly, the groups with the highest employer costs for health insurance mirror those categories with the higher participation rates. The data on incidence of participation that will be produced annually from the National Compensation Survey will be based on a sample that is about double the current ebs sample. This should enable the Bureau to publish additional geographic, industrial, occupational, and other detailed information and allow for an analysis of the link between plan participation and cost. (See Employer Costs for Employee Compensation - March 1999, cited in note 2.)
${ }^{22}$ Section $401(\mathrm{k})$ of the Internal Revenue Code authorizes private-sector, profitmaking firms (and some nonprofit organizations) to offer taxdeferred retirement plans for their workers. Section 403(b) authorizes such retirement plans for nonprofit organizations, and Section 457 authorizes plans for employees of State and local governments. Some tax-deferred retirement plans are funded solely by employee contributions, and that might explain why some respondents answered "no" to either of the first two questions about participation in retirement plans and subsequently answered "yes" to the question on participation in a tax-deferred retirement plan. When answering the first two questions, some respondents may not have considered tax-deferred plans that were sponsored, but not funded, by their employers. When, later in the supplement, these respondents were asked whether they had the option to contribute money to a plan on a tax-deferred basis, they correctly answered affirmatively. Even if a tax-deferred retirement plan does not receive employer funding, it still benefits employees because the employer provides a convenient vehicle through which employees can invest for retirement. More importantly, if the employer had not established the plan and employees instead invested their money in an after-tax mutual fund or savings account, their contributions would be subject to taxation at the time they were made, and their investment earnings would be subject to taxation at the time they were earned. Under an employer-provided plan, employees could defer paying taxes on their contributions and earnings until retirement. Even for employees who are eligible to invest in pretax individual retirement accounts at banks or other financial institutions, the limit on how much they can invest each year is much lower than under an employer-provided plan.
${ }^{23}$ Administrative figures from the Office of Personnel Management indicate that about 96 percent of Federal employees participated in either the Civil Service Retirement System or the Federal Employees Retirement

System in 1997. The considerably lower CPS estimate of 88 -percent participation among Federal employees may result from a variety of possible response errors in that survey. For example, some CPS respondents may not be aware of a household member's participation in a Federal employee retirement plan. Another possibility is that some noncovered workers employed by a private-sector contractor to the Federal Government may be classified incorrectly as Federal employees.
${ }^{24}$ The February 1995 and 1997 supplements did not include questions on plan characteristics.
${ }^{25}$ For detailed descriptions of the various types of plans and the calculation of benefits, see Ann C. Foster, "Factors Affecting Employer-provided Retirement Benefits," Compensation and Working Conditions, Winter 1998, pp. 10-17. See also William J. Wiatrowski, "Factors affecting retirement income," Monthly Labor Review, March 1993, pp. 25-35.

## ${ }^{26}$ See note 20 for references.

${ }^{27}$ A comparison of ebS data with data from the Employer Costs for Employee Compensation series indicates that employer expenditures for retirement plans are higher in groups for which coverage is more common. In the private sector, employer expenditures were higher for union workers, full-time workers in goods-producing industries, and workers in larger establishments ( 500 or more employees). Expenditures for union workers' defined-benefit plans were greater than those for their defined-contribution plans. Similarly, employer costs in larger establishments were higher for defined-benefit plans than for defined-contribution plans. Ultimately, the redesigned National Compensation Survey will provide data that will enable researchers to analyze more rigorously the relationship between employer costs and employee participation for a variety of employee benefits. See Harriet G. Weinstein, "Linking Retirement Plan Measures," Compensation and Working Conditions, Spring 1998, pp. 52-55.
${ }^{28}$ For a discussion of how the ebs estimates a worker's eligibility for, and participation in, a retirement plan, see William J. Wiatrowski, "Counting the Incidence of Employee Benefits," Compensation and Working Conditions, June 1996, pp. 10-18.

# Earnings and employment trends in the 1990s 

#### Abstract

Robust employment growth in high- and low-paying job categories was not accompanied by large wage gains; there was no apparent increase in overall earnings dispersion during the 1990s

Randy E. Ilg
and
Steven E. Haugen

Randy E. Ilg and Steven E. Haugen are economists in the Division of Labor Force Statistics, Bureau of Labor Statistics.

Earnings have long been considered an important measure of one's economic well-being, and it is widely accepted that increased earnings over time result in improved living standards. In the United States, real earnings rose sharply for several decades after World War II, but the trend slowed abruptly during the 1970 s. Although the picture during the 1980s and much of the 1990s is less clear because of different patterns among the major earnings measures, it is safe to say that there was comparatively little real wage growth during that period. ${ }^{1}$ In recent years, however, workers' real earnings have been on the rise.

The stagnation in real earnings for much of the 1990s stands in marked contrast to the considerable growth in employment during that decade. As of December 1999, the end of the period examined in this article, the current economic expansion had lasted almost 9 years. ${ }^{2}$ During that period, total employment, as measured by the Current Population Survey (CPS), grew by more than $16^{1 / 2}$ million. ${ }^{3}$

Previous research, using data from the CPS, showed that employment growth during the first half of the 1990s was concentrated in both relatively higher paying and relatively lower paying job categories, with a decline in the number of jobs paying midlevel wages. ${ }^{4}$ That same research supported the notion that there was a trend toward "polarization" in employment growth. However, it did not examine the earnings trends
in the fields associated with those categories, nor did it address whether the marked employment growth in some of the categories was accompanied by wage gains. The analysis presented herein extends the earlier work by examining the changes in both employment and earnings for all wage and salary workers over the 1989-99 period. ${ }^{5}$ Specifically, the analysis addresses the following questions: What has been the relationship between the change in employment and the change in real median weekly earnings? In particular, how have earnings changed in those job categories that posted the largest increases in employment? In addition, what happened to earnings dispersion during the 1990s, especially within the high-, middle-, and low-paying job categories?

The findings presented in the sections that follow suggest that the marked growth in wage and salary employment that took place from 1989 to 1999 in the highest and lowest earnings groups was not accompanied by a rapid rise in earnings. Earnings indeed rose, but only modestly, for both groups. In contrast, both employment and wages in the middle earnings group changed relatively little over the period. While some specific occu-pation-industry categories posted both strong employment and earnings growth, no significant correlation between employment and earnings changes was uncovered for the three major earnings groups. Finally, despite the polarization found in employment growth, earnings dispersion showed little change over the 1989-99 period. ${ }^{6}$

## Overview

The real median weekly earnings of all wage and salary workers showed little change from 1989 to 1996. In 1997, however, real earnings rose, and growth continued through 1999. As a result of these increases, there was a slight improvement in real earnings ( 6.9 percent) for the 1989-99 period. (Real weekly earnings were adjusted by means of the Consumer Price Index research series using current methods (CPI-U-RS; see box, this page). ${ }^{7}$ During those years, wage and salary employment grew by 15.5 million, or 15.0 percent, with virtually all of the net growth occurring after the 1990-91 recession. (See chart 1 and table 1.) It is important to note that the bulk of this job growth has been among full-time workers, whose share of the net growth over the past 10 years (about four-fifths) was in line with their share of total employment in $1989 .{ }^{8}$

As shown in table 1, real median weekly earnings rose in professional specialty, sales, and service occupations, but changed relatively little among the other major occupational groups, such as managers. Together, managers and professionals accounted for three-fifths of the occupational employment growth. Workers in sales and service occupations supplied most of the remaining net increase in employment.

Among the major industry groups, real earnings rose in retail trade, in services, and in the finance, insurance, and real estate industry. Real earnings changed relatively little among the other major industries. Of the total increase in wage and salary employment since 1989, most of the net growth (about four-fifths) occurred in services and retail trade.

## Occupations within industries

Employment matrix. A separate look at employment and earnings trends in major occupations and industries provides some insight into the nature of job and earnings growth, but
an examination of the changes for occupations within industries presents a more complete picture. For example, the fastgrowing services industry pays about the same as the median for all industries, but encompasses a wide array of occupations, some of which are associated with low wages, some with relatively high wages. ${ }^{9}$ The disaggregation of an industry by occupation allows one to determine, in much greater detail than at the aggregate level, which pieces of the industry are contributing to employment or earnings growth. However, analyzing the changes in employment and earnings for the nine major occupations crossed by the 10 major industries (yielding 90 data series) can be quite cumbersome. To simplify such an analysis, the data series were ordered into a more manageable format.

First, following the methods employed earlier by Ilg, the occupation-industry categories were ranked in descending order by their median weekly earnings in 1988. The categories were then classified into three groups-highest, middle, and lowest earnings - each of which accounted for approximately one-third of total employment in $1988 .{ }^{10}$ The data for the 90 individual occupation-industry categories were then sorted into the three earnings groups. Table 2 displays the employment and real median weekly earnings figures for the individual categories and the overall figures for each of the three earnings groups for the years 1989 and 1999. ${ }^{11}$

Highest earnings group. From 1989 to 1999, employment in the highest earnings group increased by 9.7 million, or about 27 percent-the most of the three earnings groups. Real median weekly earnings for the highest group showed only modest improvement. By 1999, real median weekly earnings in this group had risen by 6.3 percent, to $\$ 728$ per week.

As the U.S. economy moved out of the recession of the early 1990s and employment expanded, job growth in the highest earnings group accelerated, and strong growth continued through 1999. In contrast, real median weekly earnings for the

## The Bureau of Labor Statistics statement on the use of the CPI-U-RS

The Bureau of Labor Statistics has made numerous improvements to the Consumer Price Index (CPI) over the past quartercentury. While these improvements make the present and future CPI more accurate, historical price index series are not adjusted to reflect the improvements. Many researchers, however, expressed an interest in having a historical series that was measured consistently over the entire period. Accordingly, the Consumer Price Index research series using current methods (CPI-U-RS) presents an estimate of the CPI for all Urban Consumers (CPI-U) from 1978 to 1998 that incorporates most of the improvements made over that time span into the entire series.

The CPI-U-RS is in some ways an extension of the CPI-U-X1, an experimental series that shows what the inflation rate in the CPI-U might have been if the current rental-equivalence method of measuring the cost of homeownership had been in place prior to 1983.

The CPI-U-RS has some limitations. First, most estimates are based on bLS research covering a short period of time and extrapolated to a longer period. Therefore, there is considerable uncertainty surrounding the magnitude of the adjustments. Second, there have been several improvements in the CPI not incorporated into the CPI-U-RS, either because they do not represent changes in methodology, because they had negligible impacts on the CPI's growth rate, or because it was impossible to systematically estimate the impacts of the new methods in past years.

Nonetheless, the CPI-U-RS can serve as a valuable proxy for researchers needing a historical estimate of inflation using current (1999) methods. The direct adjustment of individual CPI index series makes this the most detailed and systematic estimate available of a consistent CPI series.

Data are restricted to wage and salary workers and exclude the selfemployed, regardless of whether their businesses are incorporated. The data include both full- and part-time workers. The Consumer Price Index research series using current methods (CPI-U-RS) was used to convert current dollars to constant dollars for 1989.
${ }^{2}$ Calculated from the rounded estimates shown.
Note: Employment growth was calculated using annual averages for 1989 and 1999.
group dipped in the mid-1990s, but earnings growth in 199799 was strong enough to produce a small gain for the period as a whole. (See chart 2.)

As might be expected, virtually all the high-paying managerial and professional occupations are concentrated in this group. Employment among managers and professionals in the highest earnings group accounted for about two-thirds of total employment in the group in 1989, but made up nearly all of the net employment increase over the 1989-99 period. Managers and professionals in the services industry expanded their ranks sharply, together accounting for about two-thirds of the employment gain in the highest earnings group. The trend in their earnings, however, was comparable to that for the overall group, declining a bit in the middle of the decade, but more than recovering toward the end. While the number of executives in construction, manufacturing, and transportation also rose substantially from 1989 to 1999, their earnings were little changed. (See table 2.)

Although managers and professionals dominate in the highest earnings group, some other occupations include a large number of high-paid workers. For example, precision production workers in manufacturing and transportation accounted
for a sizable share of employment in the highest earnings group. However, employment and earnings for both job categories changed little over the 1989-99 period.

In 1989, full-time workers accounted for slightly more than 90 percent of employment within the highest earnings group. However, full-time workers contributed a somewhat smaller share of the net increase in job growth over the 10 -year period. This difference reflects the fact that much of the overall employment growth occurred among professionals in the services industry, wherein part-time work is more prevalent than it is among professionals in other industries.

No consistent relationship is evident between employment and earnings changes in the highest earnings group over the 1989-99 period. For example, the number of executives in services rose sharply, as did their earnings. Yet, at the same time, employment among managers in transportation and public utilities also increased, but their earnings were little changed; conversely, employment among professionals in construction was little changed, but their earnings declined.

One measure that more systematically identifies the association between two variables (in this case, employment and earnings) is the simple correlation coefficient. To construct

Chart 1. Percent change in employment and real median weekly earnings of wage and salary workers, 1989-99

NOTE: The percent shown represents the percent growth or decline in annual average employment or real median weekly earnings between the year indicated and the level in 1989.
this measure, we used the percent change in employment for each occupation-industry category (weighted by its share of total employment in 1989) and the percent change in earnings. The correlation coefficient ranges from -1.0 to 1.0 , with 1.0 indicating a perfect positive relationship and -1.0 a perfect negative relationship.

For the highest earnings group, the correlation coefficient was 0.29 , which, while positive, does not indicate a high degree of association between changes in employment and changes in earnings. (The correlation coefficient for this group was not statistically different from zero at the 90-percent confidence level.) Hence, the strongest growing occupation-industry categories in the high-earnings group were not necessarily associated with the fastest earnings growth.

Middle earnings group. From 1989 to 1999, employment in the middle earnings group edged up, as growth in the second half of the period offset losses during the recession of the early 1990s. ${ }^{12}$ Employment remained below prerecession levels until 1997. Substantial job growth in 1997 and 1998, however, led to a net employment gain of some 400,000 , about 1 percent, over the entire 1989-99 period. (See chart 2.)

Real earnings in the middle earnings group drifted down for most of the period, before recovering markedly during 1997-99. In 1989, median weekly earnings were \$464 (in con-
stant 1999 dollars). After reaching a low point in 1996 (\$445), earnings rose sharply. As a result, by 1999, earnings in the middle earnings group-at \$475-were little changed from 1989. (See table 2.)

The pattern of little overall change in employment and earnings trends for the middle earnings group masked variations in several detailed occupation-industry categories. Many of these categories include blue-collar occupations in a variety of goodsand service-producing industries. Employment in some occu-pation-industry categories, such as operators, fabricators, and laborers in both construction and the transportation and public utilities industry, grew markedly over the past decade, but their weekly earnings declined. Employment declined significantly, however, among operators, fabricators, and laborers in manufacturing, while their earnings changed little.

A few occupation-industry categories other than those typified by blue-collar jobs showed substantial employment changes. The number of managers in retail trade increased, as did their earnings. Employment among technicians in the services industry also rose between 1989 and 1999, but their earnings were up only slightly. However, the number of clerical workers in manufacturing decreased, while earnings for the group increased.

As with full-time workers in the highest earnings group, full-time workers in the middle earnings group accounted for

#### Abstract

${ }^{1}$ Data are restricted to wage and salary workers and exclude the self-employed, regardless of whether their businesses are incorporated. The data include both full- and part-time workers. The Consumer Price Index research series using current methods (CPI-U-RS) was used to convert current dollars to constant dollars for 1989. ${ }^{2}$ Calculated from the rounded estimates shown. ${ }^{3}$ The overall median weekly earnings figure for the lowest earnings group has been adjusted to make it more comparable with earnings data collected

beginning in 1994. Figures for the more detailed occupation-industry categories have not been adjusted. (See note 13 in the text.)

Note: Details will not sum to totals because occupation-industry categories that had an employment base of less than 50,000 in 1989 or 1999 are not shown separately. Combined, these categories contributed only 56,000 to the net increase in employment. Data in each group are presented on the basis of change, from the largest percent increase to the largest decline. Employment growth was calculated using annual averages for 1989 and 1999.
more than 90 percent of employment in the group in 1989. But they made up just 55 percent of the small net increase in employment during the entire 1989-99 period. This difference is due, in part, to the large decline among certain manufacturing workers (operators, fabricators, and laborers; and administrative support personnel), the vast majority of whom work full time. At the same time, employment increased considerably among some occupations in the services and retail trade industries, in which part-time work is much more prevalent than in other industries.

Consistent with the variations in employment and earnings changes among the job categories in the middle earnings group, there was little correlation between the two variables. (The correlation coefficient was -0.06 , not statistically different from zero at the 90 -percent confidence level.)

Lowest earnings group. Employment in the lowest earnings group increased by 5.4 million (about 16 percent) between 1989 and 1999. Real earnings in the group rose by 11.6 percent, after adjustment. ${ }^{13}$ Employment in the lowest earnings group was relatively unaffected by the recession of the early 1990s. Indeed, through 1993, the rate of employment growth among low-wage workers actually exceeded that for workers at the upper end of the earnings spectrum. However, by the mid1990s, job growth in the high earnings group had outpaced growth in the lowest earnings group. As a result, over the entire 1989 99 period, net employment growth among low earners was about three-fifths that for the highest earnings group. As noted earlier, employment growth in both groups far exceeded that for middlewage earners. (See chart 2 and table 2.)

In 1989, median weekly earnings for the lowest earnings
group were $\$ 259$ (in constant 1999 dollars), after adjustment for the break in series associated with the CPS redesign. Following a slight decline in real earnings from 1989 to 1992, earnings in the lowest earnings group began to increase. Earnings rose markedly in 1998-99, reaching \$289 in 1999.

Employment in the lowest earnings group is largely made up of service, sales, and administrative workers, as well as operators, fabricators, and laborers, in the retail trade and the services industries. Among these occupation-industry categories, some of the fastest growing were sales and service workers in the retail trade and services industries. These categories accounted for two-thirds of the net employment increase in the lowest earnings group. Real earnings for all four categories also rose over the 1989-99 period.

Among clerical workers in the lowest earnings group, the number working in the services industry rose substantially over the period, but their earnings were up only slightly. In contrast, the retail trade industry lost administrative support workers over the 1989-99 period, but posted a substantial increase in median weekly earnings.

Compared with the shares of the highest and middle earnings groups, a much smaller share of workers in the lowest earnings group worked full time in 1989 (about three-fifths). Even so, over the 1989-99 period, a large share of the net employment gain for the lowest earnings group was attributable to full-time workers (about four-fifths). This increase reflected, in part, the strong growth in the number of full-time workers in various occupations (for example, sales, service, and administrative occupations) within the services industry.

Even though employment growth was robust in the lowest earnings group and real earnings rose, the correlation coeffi-
cient was very low, 0.10 (not statistically different from zero at the 90-percent confidence level). This underscores the weak relationship between employment and earnings changes among the occupation-industry categories in the lowest earnings group.

In sum, employment grew substantially in the highest and in the lowest earnings groups from 1989 to 1999; job growth was especially pronounced in the highest earnings group. Real median weekly earnings also rose among workers in the highand low-wage groups, with relatively more improvement among the lowest paid workers. Both employment and earnings among workers in the middle were essentially unchanged over the period. In addition, some specific occupation-industry categories in the three earnings groups posted both strong employment increases and real wage increases. However, there appears to be no systematic relationship between employment and earnings changes, as evidenced by the low correlation coefficients for the highest, middle, and lowest earnings groups.

## Earnings dispersion

In this section, we turn to the question of whether the foregoing employment and earnings developments are associated with changes in wage dispersion. As a measure of central tendency, medians serve as an overall metric for the earnings of a given group and allow one to make general inferences as to how the earnings for the group have changed over time. However, medians provide no information on the degree of dispersion in an earnings distribution-that is, how widely spread individuals are in terms of their relative earnings levels-or the extent to which the dispersion has changed.

One common method used to gauge changes in earnings

${ }^{1}$ The percentile ratios reflect adjustments to the 10 th-percentile earnings figure for each group and the 50 th-percentile earnings figure for the lowest earnings group. These adjustments make data more comparable with those beginning in 1994. (See notes 13 and 15 in the text.)
dispersion is to track various ratios of percentiles over time. ${ }^{14}$ To construct some of these ratios, the weekly earnings values associated with various percentiles (the upper limits of various deciles and quartiles) were computed for all workers and for each of the three separate earnings groups from 1989 to 1999. ${ }^{15}$ (See tables 3 and 4.) We then calculated 90th-to-10th, 90th-to-50th, and 50th-to-10th percentile ratios (the upper limit of the ninth decile divided by the upper limit of the first decile, and so forth) for all workers and for each of the three earnings groups for every year during the period.

Chart 3 suggests that earnings dispersion overall changed very little during the 1990s (after adjustment; see note 13). The 90th-to-10th percentile ratio held fairly steady. The 90th-to-50th percentile ratio edged up, while the 50th-to-10th ratio edged down, as shown in chart 4 . Thus, those at the top and those at the bottom of the distribution did better relative to those in the middle, but exhibited little change relative to each other. (Percentile ratios based on unadjusted data also are included in charts 3 and 4, to illustrate that the interpretation of recent trends in earnings dispersion is sensitive to the data used.) These findings seem to be consistent with the earnings changes previously noted for the three earnings groups, in that median weekly earnings rose for the lowest and highest earnings groups, but held steady for workers in the middle. The most notable feature of recent earnings patterns, including changes in earnings dispersion, is the relatively strong earnings growth among the lowest paid workers in 1998 and 1999.

Within the earnings groups themselves, growing dispersion was most evident in the highest earnings group. For example, the 90th-to-10th percentile ratio increased markedly over the entire 1989-99 period, reflecting strong real earnings increases among the highest paid workers in the group. It is notable that there was a slight decline in the 90th-to-10th ratio near the end of the period, because earnings advanced relatively sharply for those at the bottom rung of the highest earnings group over the 1997-99 period. (See table 5.)

The middle earnings group showed less evidence of growing earnings dispersion than the highest earnings group, and in the lowest earnings group, earnings dispersion actually declined. It is worth noting again that the lower paid workers in each of these groups also saw their earnings rise slightly from 1997 to 1999.

WAGE AND SALARY EMPLOYMENT GREW SUBSTANTIALLY from 1989 to 1999. Nearly all of the growth was concentrated among relatively high- and low-paid workers, with the strongest job growth occurring in the highest earnings group. There was scant employment growth among workers with midlevel wages. Real median weekly earnings for the highest and lowest earnings groups also showed some improvement over the entire period, largely due to the marked acceleration in earnings growth toward the end of the decade. It is notable that the earnings growth was somewhat more pronounced among workers in the lowest earnings group. Despite a similar pickup in real median weekly earnings in the middle earnings group in the late 1990s, earnings remained about unchanged over the entire period.

Among the more detailed occupation-industry classifications, there was little correlation between those that grew the fastest in terms of employment and those that registered rising wages. While some individual occupation-industry categories had both strong employment growth and strong earnings growth, others showed divergent employment and earnings trends, and still others showed declines in both employment and earnings. These widely different patterns were pervasive throughout the range of detailed oc-cupation-industry categories analyzed.

Finally, given the distinct polarization in employment growth from 1989 to 1999 and the absence of substantial overall earnings growth, we examined the data for changes in the earnings dispersion. After adjusting for breaks in weekly earnings series associated with the redesign of the CPs in 1994, we did not discern a general rise in earnings dispersion over the 1989-99 period.

## Notes

Acknowledgment: The authors thank Anne E. Polivka, of the Office of Employment and Unemployment Statistics, Bureau of Labor Statistics, for deriving adjustment factors used in this article to address the breaks in various CPS weekly earnings data series associated with the 1994 survey redesign.
${ }^{1}$ For an analysis of trends in various wage series from the Current Population Survey, the National Income and Product Accounts, and the Current Employment Statistics survey, see Katharine G. Abraham, James R. Spletzer, and Jay C. Stewart, "Why Do Different Wage Series Tell Different Stories?" American Economics Association Papers and Proceedings, May 1999, pp. 34-39.
${ }^{2}$ The official end of the last recession, as determined by the National Bureau of Economic Research (NBER), was March 1991. Under NBER's method for determining the length of an expansion or recession, the economic trough, in March 1991, would be counted as the first month in the current economic expansion. The economic peak (when it occurs) would be counted as the first month in the subsequent economic recession. The longest expansion on record, 106 months, occurred during the 1960s. As of December 1999, the current economic expansion also appears to have lasted 106 months.
${ }^{3}$ The CPS is a nationwide sample survey of approximately 50,000 households conducted for the Bureau of Labor Statistics by the Bureau of the Census. The cPs provides information about the employment status and demographic and socioeconomic characteristics of the civilian noninstitutional population aged 16 and older. The major gauge of employment growth is the Current Employment Statistics (CES) program, a bls survey of more than 400,000 business establishments. However, this survey does not supply data on the occupational characteristics of employment, an essential feature of the research presented in this article. From March 1992 to December 1999, a period of sustained job growth following the 1990-91 recession, the ces survey showed a job gain of about 22 million, well above the $16^{1 / 2}$ million indicated by the CPS. (Both estimates are based on changes in seasonally adjusted data). Numerous conceptual and methodological differences between the two surveys could account for these differences in measured employment growth. For a recent study of this issue, see Mark Schweitzer and Jennifer Ransom, "Measuring Total Employment: Are a Few Million Workers Important?" Economic Commentary (Federal Reserve Bank of Cleveland, June 1999).
${ }^{4}$ See Randy E. Ilg, "The nature of employment growth, 1989-95," Monthly Labor Review, June 1996, pp. 29-36.
${ }^{5}$ Employment and earnings data analyzed in this article are based on the Outgoing Rotation Group files from the cPS. Median weekly earnings for all wage and salary workers, both full and part time, are analyzed, unless otherwise noted. Self-employed workers are excluded, regardless of whether their businesses are incorporated. (Earlier research by IIg, cited in note 4, analyzed total employment, including the self-employed.) The year 1989 was chosen as the beginning year for the analysis presented herein because labor market activity at the end of the 1980s resembled that of the late 1990s and also because 1989 was sufficiently removed from the influence of the recession that started in mid-1990.
${ }^{6}$ Some of the earnings data presented in the article have been adjusted for breaks in series associated with the introduction of the redesigned CPS in 1994. Adjustments were made to median weekly earnings for the lowest earnings group and for earnings at the 10th percentile for all workers and each of the three earnings groups. The rationale for making these adjustments is discussed in detail in notes 13 and 15 .
${ }^{7}$ See Kenneth J. Stewart and Stephen B. Reed, "Consumer Price Index research series using current methods, 1978-98," Monthly Labor Review, June 1999, pp. 29-38. The increase in real median weekly earnings in 199799 is particularly noteworthy. A change in real earnings can occur because either nominal wages or the rate of inflation (or both) changed. Throughout much of the 1990 s, the annual rate of increase in the CPI-U-RS was about equal to that of nominal earnings. From 1997 to 1999, the rate of inflation was well below levels seen earlier in the decade, while the increase in nomi-
nal earnings improved. Other earnings measures, such as average weekly earnings for private production or nonsupervisory workers from the CES program, showed a similar pattern.
${ }^{8}$ For the purposes of this article, full-time workers are those who usually work 35 hours or more on their principal job.
${ }^{9}$ For additional information on the employment diversity in the services industry, see Joseph R. Meisenheimer II, "The services industry in the 'good' versus 'bad' jobs debate," Monthly Labor Review, February 1998, pp. 22-47.
${ }^{10}$ The methodology used was adopted from that employed in previous research on job growth. (See Ilg, "The nature of employment growth.") Earnings data for 1988 were chosen for purposes of ranking the individual occu-pation-industry categories, because that year was outside the period of study, but representative of the level of economic activity throughout much of the 1989-99 period. Similarly, data for 1988 were used as the basis for splitting employment into three groups of nearly equal size. The groups do not necessarily contain exactly one-third of wage and salary employment, because an occupation-industry category that fell on the dividing line between groups was not split, but rather, was included in the group into which most of its employment fell. Sensitivity testing has shown that ranking the occupationindustry categories by earnings from other years may influence those categories on the boundary of the major earnings groups. That is, some categories tend to move in or move out of the major earnings groups, based on which year is chosen for purposes of ranking. However, using earnings from other years to rank the occupation-industry categories also shows that the trends in employment growth for all earnings groups were similar to those presented in this analysis, although the magnitudes of the changes differed somewhat.
${ }^{1}$ Occupation-industry categories that had an employment base of less than 50,000 in either 1989 or 1999 are not shown separately in the table, because the earnings estimates for relatively small groups are generally associated with relatively large standard errors. Employment and earnings data for these categories with fewer workers are, however, included in the totals for the highest, middle, and lowest earnings groups. Combined, the 21 occu-pation-industry categories (out of the total of 90 ) accounted for a negligible portion of the net increase in employment between 1989 and 1999. Data are ranked in descending order by percent change in employment. The annual estimates of employment and earnings for the nine major occupations and 10 major industries from 1989 to 1999, as well as the 90 individual data series, are available from the authors upon request.
${ }^{12}$ The reader is cautioned that the middle earnings group is not intended to represent the "middle class." While many studies have documented the erosion of the number of persons, households, or families in the "middle" of the distribution of incomes (a trend often characterized as the "declining middle class"), this article does not attempt to shed further light on that issue.
${ }^{13}$ In January 1994, a new questionnaire and survey methodology were introduced into the CPS. The survey questions on earnings were modified substantially, to improve the quality of the data. While estimates of overall median weekly earnings were not materially affected by the redesigned survey, the impact on earnings data for persons at the bottom of the weekly earnings distribution was significant. In particular, changes to the survey in 1994 led to lower reported earnings for relatively low-paid workers, compared with pre-1994 estimates. To account for this break in the various series, median weekly earnings figures for the lowest earnings group over the 1989-93 period have been adjusted to reflect the methodology used in 1994 and later years. After adjustment, the real median weekly earnings for the lowest earnings group for the years 1989-93 are somewhat lower than the unadjusted figures for those years, resulting in a slightly larger percent change over the entire 1989-99 period ( 11.6 percent, as opposed to 7.8 percent before adjustment). Because of the very small sample sizes, no attempt was made to adjust the earnings series for the detailed occupation-industry categories in the lowest earnings group. (The adjustment factors were produced specifically for this article by Anne E. Polivka of the Bureau of Labor Statistics and were derived using methods she has developed as part of ongoing
research. See Anne E. Polivka, "Using Earnings Data from the Current Population Survey after the Redesign," Bureau of Labor Statistics, working paper 306, January 1999. The adjustment factors are available from the authors upon request.)
${ }^{14}$ Percentiles for any wage or income distribution are calculated by ranking earnings observations from lowest to highest and then determining the earnings level for the upper limit of a given percentile cutoff. For example, 10 percent of earnings observations are below the upper limit of the 10 th percentile (or first decile). For a recent analysis and discussion of wage inequality, see, for example, Paul Ryscavage, Income Inequality in America (New York, M.E. Sharpe, 1998); see also Jared Bernstein and Lawrence

Mishel, "Has wage inequality stopped growing?" Monthly Labor Review, December 1997, pp. 3-16.
${ }^{15}$ As explained in note 13, in this article earnings data for the 1989-93 period have been adjusted (where applicable) for breaks in series associated with the redesign of the CPS in 1994. With respect to various percentiles, research has shown that the upper limit of the first decile for all workers was significantly lower, as measured under the redesigned survey; hence, data for the 1989-93 period have been adjusted (downward) to make them more comparable. In addition, the first decile was adjusted for each of the three individual earnings groups. As mentioned in note 13, the 50th percentile (median) for the lowest earnings group also required adjustment.

## Where are you publishing your research?

The Monthly Labor Review will consider for publication studies of the labor force, labor-management relations, business conditions, industry productivity, compensation, occupational safety and health, demographic trends, and other economic developments. Papers should be factual and analytical, not polemical in tone.

We prefer (but do not require) submission in the form of an electronic file in Microsoft Word, either on a diskette or as an attachment to e-mail. Please use separate files for the text of the article; the tables; and charts. We also accept hard copies of manuscripts.

Potential articles should be mailed to: Editor-in-Chief, Monthly Labor Review, Bureau of Labor Statistics, Washington, DC 20212, or by e-mail to mlr@bls.gov

# Transportation by air: job growth moderates from stellar rates 

Aviation employment and business activities increased massively for decades, but growth slowed in the '90s

William C. Goodman

William C. Goodman is an economist in the Office of Employment and Unemployment Statistics, Bureau of Labor Statistics.

Commercial air transportation has grown rapidly in the United States since 1938 or earlier. ${ }^{1}$ The most significant reason for such growth is probably that air travel has become almost continuously more affordable. Ticket prices adjusted for inflation have been falling consistently since 1950 or earlier. ${ }^{2}$

Airfares have decreased over the years not because of any one consistent reason, but because of two distinct sets of circumstances: regulation and deregulation. From 1938 to 1978, Federal control of fares, routes, and even the existence of each airline prevailed. After the lifting of economic regulation, price competition was a major force. Before 1978, development of the commercial airplane itself contributed heavily to decreases in the costs of operations and consequently to lower fares (after adjustment for inflation). After 1978, when changes in routes and fares and the formation of new airlines became unrestricted, price competition and a variety of management responses to competition have reduced operators' costs. The resulting lower fares have multiplied demand and jobs in the industry.

According to estimates from the Bureau of Labor Statistics, ${ }^{3}$ employment in commercial aviation increased by about 700,000 jobs, or more than 400 percent, from 1958 to 1996 as output, consisting mainly of passenger-miles and cargo ton-miles, increased by more than 1,800 percent. ${ }^{4}$ Although the main purpose of this article is to explain the trend in numbers of jobs in the industry, the movement of aviation output is cited often. Some industries have been known to lack a close connection be-
tween production and employment; thoroughly automated processes in certain industries may explain the possibility of little connection between volume of production and number of employees. The aviation industry, despite its great technological advances, remains a service industry, and is labor-intensive. According to the Air Transport Association, ". . . there is no changing the fact that they [airlines] are in a service business where customers require, and often demand, a lot of personal attention. More than one-third of the revenue generated each day by the airlines goes to pay its workforce." ${ }^{5}$ This article shows the extent to which employment and production are linked in the aviation industry.

Despite the massive cumulative increases of output and employment, the growth of both decelerated; recent increases have been at reduced rates. This article explains some of the many technological, legislative, and business changes that have caused the growth and the deceleration of the industry.

## Economic performance

The amount of growth that has occurred in the industry's jobs and business, both in isolation and in relation to other transportation industries, the general economy, and U.S. international trade, is extraordinary. To give one of many possible perspectives, from 1971 to 1997, the proportion of U.S. adults who had ever traveled by an airliner increased from less than half ( 49 percent) to 81 percent. According to surveys from the Air Transport Association of America, the proportion of adults who

## Trends in the former and current estimates of air transportation employment, 1988-96

Within the transportation division, establishments are assigned to a specific industry based on the main economic activity of the entire company. In 1996, a considerable number of establishments engaged in express delivery of letters and packages were re-evaluated regarding the industry in which they properly belonged. Most of the establishments in question had been considered members of the trucking industry; a smaller number had been assigned to the transportation services industry. In 1997, these establishments were reassigned to the air transportation industry. Estimates of employment in trucking were reduced, and estimates of employment in transportation by air were increased. Each of the two changes was on the order of 250,000 jobs. Because of the significant break in the aviation employment data, the old series, which is analyzed in this article, was terminated in 1997. On the basis of the changes in industry classification, new estimates of employment in trucking and in transportation by air were calculated from microdata back to the year 1988.

The revision in the estimated number of employees in transportation by air is large enough so that estimates for years prior to 1988 , available only in the old series, are not compatible with estimates from the new series for purposes of analyzing the trends of the industry. To analyze the
growth of employment in airlines over several decades, starting in 1958, analysis of employment in this article is generally confined to the use of the old series of estimates.

Despite the difference in magnitude between the old series and the new one, the 8-year trend of the old series in terms of percent employment growth agrees with the new series' trend during the period of overlap, from 1988 to 1996. Although the two time-series show differing percent changes in various individual years, the two estimated aggregate percent changes from 1988 to 1996 are within 1 percentage point of each other. (As shown below, the aggregate growth in employment is estimated at 31.1 percent in the discontinued series and 30.2 percent in the new series.) Average annual percent growth during the 8 -year period is 3.4 percent in each of the two series.

An indication of growth in jobs in years after 1996 is provided only by the new series. From 1996 to 1999, growth accelerated somewhat to 3.8 percent per year from 3.4 percent in the preceding 8 -year period.

The recent growth, however, is clearly slower than that of still earlier years as estimated by the old series. In the 31year period through 1989, employment grew by an average of 4.7 percent per year, sharply differing from the more recent 3.8 percent rate.

Comparison of two sets of estimates of employment in transportation by air, 1988-99

| Year | Old series |  | New series |  |

| 1999 ............................................. | $\ldots$ | $\ldots$ | 1,237 | 4.6 |

had traveled on an airliner in the latest 12 months increased from 21 percent to 39 percent during the period. ${ }^{6}$

Between 1960 and 1996, the output of the air transport industry increased sixteen-fold. By comparison, the output of the entire business sector only increased by a factor of 3.6. Total passenger-miles of all major forms of transportation tripled, and domestic ton-miles of all major modes of freight transportation increased 1-1/2 times. (See chart 1.) ${ }^{7}$

Substitution? Most modes of transportation have grown during the last 40 years. But to a considerable extent, aviation has taken over the roles of other forms of travel in the typical American life; flight is now a more frequent experience, and most other major modes of passenger transportation have not kept up with the growth of the general economy. The only large category of U.S. transportation to show an actual reduction of business in recent decades is rail passenger transport, which lost 12 billion annual passenger miles from 1960 to 1996. Even if all those who previously traveled by train now travel by air, the loss in rail passenger transport would explain only 3 percent of the increase in domestic air passenger business. In 1960, air transport was 2 percent of all U.S. domestic passen-ger-miles (including the use of private automotive vehicles); air transport rose to 10 percent of the total by 1996. The following tabulation compares changes in the volumes of the major passenger modes from 1960 to 1996. (Over the same period, by comparison, gross domestic product in chained 1996 dollars increased by 231 percent.) ${ }^{: 8}$

| -12 | -70 |

In contrast to air passenger service, air cargo has not taken the role of any other mode of freight transportation to any large extent. All three domestic surface modes of freight transportation (truck, rail, and water) operate on a much greater scale than air transportation of freight and have shown much more massive growth. The increase in domestic air freight tonmiles since 1960, though large as a percentage of its 1960 level, is about 12 billion ton-miles, while intercity trucking, domestic water, and rail freight have each increased by between 350 billion and 785 billion ton-miles. Similarly, the scale of international air cargo has been insufficient to affect the growth of the much vaster operations of international water cargo by much. Aviation has not seriously reduced the growth of any
major mode of freight transportation.
It is true, however, that the percent increases in international air cargo and domestic air cargo are not nearly approached by the other modes. The following tabulation shows rates of growth in the major forms of freight transportation.?

| Mode | Increase in ton-miles |  |
| :--- | :---: | ---: |
|  | In billions | In percent |
| 1960-96: |  |  |

| International air cargo ................ | 7 | 502 |
| International water tonnage |  |  |
| (ton-miles not available) ......... | 455 million tons | 78 |

Deceleration. The growth of output in air transport, however, has decelerated over the decades. The output of the industry increased by 648 percent, or 10.6 percent per year, from 1958 to 1978. A closer look shows that growth was concentrated in the earlier part of the period and slowed to a 6.0-percent rate in the 10 years ending in 1978. From 1978 to 1996, output increased by 5.5 percent per year. From 1986 to 1996, output gained a further decelerated 5.0 percent per year. ${ }^{10}$ Some, but not all, of the deceleration is attributable to reduced growth in the business sector as a whole. The following tabulation shows the relationship between growth of output in air transport and increases in output in the entire business sector.

Percent change per year in output

|  | Air transport <br> (a) | Business sector (b) | Ratio of <br> (a) to (b) |
| :---: | :---: | :---: | :---: |
| 1960-70 | 14.3 | 4.3 | 3.3 |
| 1970-80 ............................. | 6.0 | 3.5 | 1.7 |
| 1980-90. | 6.1 | 3.4 | 1.8 |
| 1990-96 ........................... | 4.4 | 3.0 | 1.5 |

Further explanations for the deceleration in air transport business, and in turn for the deceleration of employment in aviation, have to do with the history of aviation technology, regulation by the Federal Government, and the airlines' operational methods. Other explanations relate to general economic deceleration. The technology, regulation, and business strategies of the industry have changed greatly; major changes will be explained in later sections of this article.

Growth of subdivisions of air transport. The various categories of air transport (freight, passenger, domestic, and in-

Chart 1. Aviation output and business-sector output, 1959 to 1996

Chart 2. Output and employment in transportation by air, 1958 to 1996

ternational) have grown at far different rates. Air cargo has increased much more rapidly, in percent terms, than passenger flight. From 1970 to 1996, while passenger-miles almost quadrupled, air cargo ton-miles increased to about six times their 1970 level. One explanation for the rapid growth of air cargo may be the growth of catalog and mail-order retailers, who often offer express delivery by air. From 1982 to 1995, the output of such catalog and mail-order retailing increased by 222 percent, while the output of the entire business sector increased by 61 percent. ${ }^{11}$ In the domestic market for freight transportation, relative costs are a factor; from 1960 to 1996, the cost of domestic airfreight adjusted for inflation declined, while the cost of class 1 intercity trucking increased. ${ }^{12}$ Greater international trade is another explanation for the growth of air cargo, as discussed later in this article.

The transportation of passengers may be divided between business travel and personal travel. Both business trips and personal trips have increased substantially, but the growth of personal travel has been greater. From 1977 to 1997, business trips increased by 125 percent, but personal trips increased by 175 percent. As personal travel is more sensitive to fares, the long-term decline in fares is a more important factor in personal flights than in business trips.

Within the broad category of reasons for personal travel, the specific reason that showed the most dramatic gain was sightseeing and resort use. Travel to resorts and the sights motivated trips for 20 percent of air travelers in 1977 and 31 percent in 1997. Flying to visit friends or relatives also increased as a proportion of air travelers' purposes. In 1977, 53 percent of air travelers flew to visit people; in 1997, 71 percent did. (Some individuals took more than one trip for more than one personal reason.) ${ }^{13}$

Growth: domestic versus international. Within the category of passenger transport, domestic flight contributed most of the increase in business because domestic operations constitute the bulk of the passenger business. But international business grew proportionately more. From 1960 to 1996, domestic passenger miles increased by 1,293 percent ( 395 billion passenger miles), and international passenger-miles increased by 1,741 percent ( 145 billion passenger-miles). ${ }^{14}$

From 1983 to 1996, the number of overseas visitors to the United States nearly tripled (a 189-percent increase), reaching a level of 22.7 million arrivals in 1996. Trips to the United States by overseas residents grew to outnumber overseas trips from the United States by U.S. residents, during the period. While a single trip can have more than one purpose, a nearly constant percentage of visitors from overseas ( 32 percent in 1983 and 31 percent in 1996) performed business or professional activities in the United States. The proportion that visited friends or relatives in the United States also was stable at 30 percent to 31 percent. The percentage indulging
in leisure activities during at least part of their stay increased substantially, from 47 percent in 1983 to 63 percent in 1996. Growth in visits to the United States appears to be concentrated among those motivated by leisure and recreational activities. ${ }^{15}$

Among U.S. residents flying overseas, growth in trips has the opposite concentration in motive. All major categories of activity contributed to an overall 103-percent increase in overseas flights by U.S. residents, but the proportionately greatest increase was in work and work-related activities. Those performing business or professional activities overseas increased from 27 percent of the total in 1983 to 36 percent in $1996 .{ }^{16}$

In freight transport as well, domestic service is greater in scale than international service and contributed a larger increase in ton-miles. From 1970 to 1996, domestic air cargo increased by 10.7 billion ton-miles, and international ton-miles increased by 7.4 billion. But, as in passenger service, international freight increased at a greater percentage rate ( 567 percent) than domestic freight ( 488 percent).
The enormously increased share of international, as opposed to domestic, business in general requires more air travel, including both cargo transport and passenger flight for business purposes. International cargo traffic is also boosted by manufacturers' "just-in-time" approach to inventory, which became widespread in the 1980 s and 1990 s, and by recent consumer demand for fresh foods of all kinds regardless of the season. ${ }^{17}$ The following tabulation shows the increasing proportions of international business as a part of the U.S. economy. ${ }^{18}$

| U.S imports as a | U.S exports as a |

| product | product |

| 1960 ............................ | 4.6 | 3.7 |
| :---: | :---: | :---: |
| 1970 ............................ | 6.3 | 4.5 |
| 1980 ......................... | 6.7 | 6.8 |
| 1990 .. | 9.5 | 8.6 |
| 1996 ...................... | 12.3 | 11.2 |

Jobs. Employment of airline personnel is linked tightly to air transport output. Ninety-nine percent of the variation in numbers of employees from 1958 to 1996 can be predicted on the basis of industry output, according to a regression calculation. Chart 2 shows that the curves representing output and employment over time have similar shapes.

The number of jobs added and the amount of output added each year, however, have not been in a constant proportion to each other. Over time, fewer employees are hired for a given amount of additional business because technological and operational progress allows for the more efficient use of both old and new employees.

Like output, employment in the industry has grown almost every year since 1958. From 1958 to 1996, despite various mass layoffs, mergers, and failures, employment in the air transportation industry as a whole increased from 165,000 to 847,000 , a 413-percent increase, or an average of 4.4 percent per year. (See table 1.)
Not surprisingly, employment in air transportation has expanded at a far greater rate than employment in other modes of travel. Aside from the much greater percent increases of business in air transportation, another major factor contributes to the differences in hiring: employment in rail and water transportation declined even as ton-miles increased. Percent increases or decreases in jobs by mode are shown in the following tabulation:

| Mode | Year | Employment change inpercent |
| :---: | :---: | :---: |
| Rail ...................................... | 1958-96 | -76 |
| Water ................................... | 1964-96 | -24 |
| Air. | 1958-96 | 413 |
| Trucking and warehousing | 1988-96 | 21 |
| Air .................................... | 1988-96 | 31 |

A deceleration is evident in aviation employment. While jobs increased by 4.6 percent per year from 1958 to 1978, from 1978 to 1996 they increased by 4.1 percent per year. From 1990 to 1996 , the rate of increase slowed to 2.2 percent. The following tabulation shows the relationship between growth in avia-tion-industry jobs and all nonfarm payroll jobs:

|  | Annual percent change in jobs |  | Ratio of percent growth in air transportation to percent growth |
| :---: | :---: | :---: | :---: |
|  | Air transport | Total nonfarm | nonagricultural industry |
| 1958-78 | 4.6 | 2.7 | 1.7 |
| 1978-96 | 4.1 | 1.8 | 2.3 |
| 1980-90 ................. | 5.1 | 1.9 | 2.7 |
| 1990-96 ................. | 2.2 | 1.5 | 1.5 |

In proportion to the general economy, then, jobs in transportation by air have not increased as strongly in the 1990s as they had in earlier decades.

Estimates from the Bureau of Labor Statistics permit the comparison of rates of job growth in the following subdivisions of the aviation industry since 1988: scheduled passenger service, air courier service (the carrying of letters and small parcels), nonscheduled air transportation, and support services, including the operation of airports and the servicing of aircraft. The following tabulation shows rates of growth in employment by industry from 1988 to $1998 .{ }^{19}$

| SC | Industry | Percent increase in employment | Increase as a percentage of entire increase in jobs in transportation by air |
| :---: | :---: | :---: | :---: |
| $\begin{aligned} & 45 \\ & 4512 \end{aligned}$ | Transportation by air .. Scheduled air transportation (passenger and cargo, over regular routes on regular | 39 | 100 |
| 4513 | schedules) ................. <br> Air couriers (letters, parcels, and generally smaller packages) ....... | 70 | 59 |
| 452 | Nonscheduled transport (nonscheduled cargo, charter, and others) .... | 137 | 8 |
| 458 | Support services (airports, flying fields, services) $\qquad$ | 48 | 13 |

The faster recent growth of cargo transportation, as opposed to passenger traffic, is reflected in the more rapid growth of air couriers (who carry only letters, parcels, and packages) and nonscheduled transport (which is dominated by cargo). Scheduled air transportation, on the other hand, is dominated by the more slowly growing passenger traffic. The rapid growth of support services such as airport operations is explained in part by the building up of airport facilities to handle greater cargo traffic. ${ }^{20}$

Layoffs in recessions. During and soon after the last three recessions (over the years 1980 to 1991), layoffs in the industry have been proportionately much more severe than those of the entire nonfarm sector. (See table 2.) Because personal air travel is generally not a necessity, individuals may be more likely to sacrifice it as opposed to other goods or services. The consistently thin financing of the airlines also makes layoffs and company failures more difficult to avoid. ${ }^{21}$

After the recession of 1969 to 1970 (and to a lesser extent, after the recession of the mid-1970s), air transport employment continued to fall well after the official end of the recession and the upturn of total employment. In the case of the 1969 to 1970 period, the decline in airline employment also started before the recession. In both periods, the declines were not strictly recessionary, as various special problems then affected the industry. (See the section on deregulation later in this article.)

In the latest recession, the loss of jobs in air transportation was almost entirely in scheduled air transportation (sic 4512, losing 24,000 jobs). Air couriers (sic 4513) expanded in employment at a reduced rate during the recession; they gained 19,000 jobs in the 12 months just before the recession and

Table 1. Comparison of employment in air transportation and in all nonagricultural industry, 1958-96

gained 5,000 during the recession. Airports, flying fields, and services (sic 458), previously gaining about 7,000 jobs per year, stopped growing, but lost only 1,400 jobs during the recession. It appears that scheduled passenger service is the component most vulnerable to economic layoffs.

Quality. An increasing volume of complaints in recent years indicates that the flight experience is more often unpleasant. Complaints have been about less spacious configurations, ". . . unexplained delays, baggage hassles and crowded cabins. ${ }^{י 22}$ Unlike other aspects of the industry, the quality of the flight experience is difficult or impossible to quantify ${ }^{23}$ Exactly how to weight less comfortable flights against seriously lower prices is unclear.

## Technological progress

By 1958, economic regulation of the industry was well established and effectively prevented price competition. Airlines therefore had incentive to compete and advance in aspects other than fares. Between 1958 and 1978 (as well as earlier), the large civil aircraft typically in use changed greatly. Its improvements both appealed to the general public in and of themselves and lowered operational costs. Although prices did not vary between airlines at a given point in time, cost savings achieved through more advanced aircraft were passed on to passengers in the form of substantially declining ticket prices after adjustment for inflation. Two changes to the aircraft were of particular economic importance. First,
aircraft consistently became larger, so that more travelers could share the cost of a particular flight. From 1960 to 1978, the average number of passenger seats per plane increased from 66 to $146 .{ }^{24}$

Secondly, aircraft became faster because of the gradual transition from propeller-generated thrust to jet power, starting in the late 1950s. ${ }^{25}$ A much faster craft could make more runs in a given amount of time, so that the crew and the plane became more productive; consequently, the average cost of a flight declined. Furthermore, at the time, jet fuel cost about half as much as the gasoline used in piston aircraft engines. Faster travel also was more attractive to passengers, and demand increased because of quicker trips and because of lower prices.

Perhaps surprisingly, wide-bodied aircraft, introduced in $1969,{ }^{26}$ represented the last major technological change in the craft to have major economic consequences. After the late 1970s, technological advances in civil air transport have continued, especially in the areas of fuel efficiency and noise reduction, ${ }^{27}$ but have been less economically important than earlier developments. By the late 1970s, the transition to jet power among the major airlines was already accomplished. The size of the average airliner in passenger service (in terms of the number of seats) peaked in 1983, when the average craft had 165 passenger seats. The average number of seats then declined to 152 in 1996. ${ }^{28}$

An initiative to build a domestic supersonic jet for passenger service ended in 1971 because of the issue of sonic booms traveling over populated areas. No U.S. airline has ever operated a supersonic craft. ${ }^{29}$ Airlines have continued to improve in fuel efficiency, emissions control, and noise abatement. ${ }^{30}$

If the further development of civil aircraft had less economic importance after 1978, a certain earthbound type of technological system did have considerable economic impact. Computer-based reservations systems made reservations bookkeeping more efficient. Certain major airlines shared systems, generating still greater efficiency. Travel agents' electronic access to the airlines' reservations systems further facilitated the sales process. Most recently, customers can check
fares and make reservations via the Internet.
More importantly, computers are well suited to a much more sophisticated use. Although ticket pricing had been simple before the late 1970s (typically divided into only two classes: first and coach), modern computer reservations systems enable airlines to provide a complicated and rapidly changing set of prices for better economic advantage.

Computerized reservations systems facilitate benefiting from the differing natures of two types of demand: business travel and personal travel. Generally, the executive on a business trip has an inflexible schedule and relative indifference to ticket prices. The pleasure traveler has more time to spend on layover, more ability to adapt to unpreferred times and dates of travel, and more sensitivity to prices. With computer reservations systems, the airlines can rapidly formulate and implement lower fares with certain restrictions in scheduling, typically required stayovers, to attract more pleasure travelers. The computer systems also quickly calculate higher fares with freer scheduling to attract executives on business.
In addition, tickets tend to become more valuable as the flight becomes more filled and as the date of travel approaches. Computer reservations systems enable the airlines to recalculate fares rapidly in accordance with the changing supply and demand for seats on a particular flight. ${ }^{31}$ The industry has succeeded in filling more seats by means of varying fares; therefore more passengers share the cost of a flight, bringing down average fares and consequently aiding growth as average ticket prices fall.

## Deregulation: new ways of competing

After the 1970s, fares continued to fall, even though technological changes had much less economic impact. The reasons for the continued reductions of fares are mainly related to the end of most of the Federal Government's economic control of air transport.

Federal control of fares and allocation of routes can be traced back to 1938, when Congress created the Civil Aeronautics Authority to foster satisfactory air service. The theory

Note: Recessions are designated by the National Bureau of Economic Research.
that excess, disorderly competition would be bad for the industry exerted a crucial influence on Congress. Unregulated start-ups of an unlimited number of operators theoretically would have resulted in so much competition that any particular airline would be unable to attract the capital required to offer good, sustainable service. A certain degree of concentration of capital was believed to be necessary for the development of adequate airlines. "Chaotic competition" had been a great problem in the 1920s in various industries. The Civil Aeronautics Act of 1938 and the Federal Aviation Act of 1958 provided government control of fares, of the creation of any new interstate airlines, and of allocation of routes among airlines. ${ }^{32}$ The airlines were to be protected from too many competitors and destructive price slashing.

The Civil Aeronautics Board, the agency created by Congress to regulate the airlines economically, prevented cuts in fares in several ways. First, considerable advance notice of a change in fare had to be given to the board, alerting competitors and thereby reducing the financial incentive to cut fares. The board also disallowed the formation of new airlines; from 1950 to 1974,79 companies submitted applications to start airline service, but none of the applications were approved. Furthermore, starting in the late1960s, the Board's rules effectively required an airline to change fares, if it did so, on all of its routes rather than selected ones. The result was that fare cuts seldom occurred after $1968 .{ }^{33}$ The government not only set rates, but also held down the number of carriers servicing most routes to three or fewer, greatly reducing the potential competition. (Despite these problems, airfares adjusted for inflation did decline substantially and almost continuously during the period of regulation, but perhaps not as much as they could have.)
With no competition on price, airlines competed on amenities and on convenience, meaning frequency of scheduled flights. Routine flights, including coast-to-coast ones, by about half-empty planes became a recognized example of vast waste. At least theoretically, such wasteful practices at the expense of travelers would be seriously reduced by unrestricted market entry and price competition.

Why Congress deregulated airlines. Various economic papers from as early as the late 1950s suggested that price competition in air transport would seriously lower fares. ${ }^{34}$ Deregulation did not occur, however, until the combination of three economic events contributed to widespread public dissatisfaction with air travel and passage of the Airline Deregulation Act of 1978. First, the Arab oil embargo of 1973 was followed by huge increases in fuel costs. The price of jet fuel climbed greatly through 1981. Secondly, the recession of the mid-1970s reduced growth in airline business and contributed to a downturn in airline volume in 1975. And third, the carriers' financial vulnerability was worsened because carriers had recently in-
curred the expense of newly developed wide-bodied aircraft and were unable to fill them. To protect the airlines, the Civil Aeronautics Board allowed considerable increases in fares (the price of a passenger-mile, not adjusted for inflation, rose by a third from 1973 to $1978^{35}$ ) and allowed carriers to reduce service. The public response to higher prices and scarcer seats was unfavorable. Prominent Senate subcommittee hearings spread the idea that ticket prices would be reduced significantly under free competition. Fares, including the cost of moving freight as well as people, availability of seats, and the financial soundness of the carriers, then, were the key issues in a historic reversal of government policy. ${ }^{36}$
Starting in late 1977, cargo carriers were allowed to set their own prices and fly any domestic route. The Airline Deregulation Act passed in October 1978, and by late 1979, "carriers were able to launch just about any domestic service they wanted"and decide on their own ticket prices. ${ }^{37}$ New providers of domestic airline service also were permitted to start operations; the number of carriers using craft with over 60 passenger seats more than tripled from 1978 to $1984 .{ }^{38}$ International air service, however, was not deregulated, as the various governments did not agree to do so.

In retrospect, two of the developments that caused deregulation were of relatively short duration or were misperceived. The large increases in ticket prices were perhaps the most important immediate motivation, yet they were arguably illusory. The nominal price increases near the end of regulation, from 1973 to 1978, were indeed large, but adjustment of the fares for general inflation (using the Consumer Price Index or CPI) shows that real prices of airline tickets continued to fall even in that time, despite the Arab oil embargo. Adjusted for inflation, airfares fell by 2.3 percent per year from 1973 to 1978. The downward trend in real prices in the 5-year period, then, was at about the same rate as in the preceding years. ${ }^{39}$
The mid-1970s recession, which in reducing airline business led to fears about the airlines' financial survival, ended in 1975. Even during the recession, airline business (as measured by output) declined in only one year, 1975, the final year of the recession. In 1976, still under regulation even if regulation was eased in policy, airline-industry output (consisting primarily of passenger-miles and cargo ton-miles) rose by 10 percent and reached an all-time high, as it had in every year since 1948 except for 1975 . Two of the immediate motivations for deregulation (rising fares and declining business), then, were arguably illusory reasons for a permanent change in policy.
Changes in economic trends of the industry clearly occurred soon after deregulation. Greater competition, generating lower prices and consequently greater demand, was a major development. The number of carriers was obviously affected. Soon after passage of the Airline Deregulation Act, entrepreneurs did indeed respond to the sudden possibility of flying routes at will. The number of major, national, and regional airlines had
decreased from 52 in 1971 to 43 in 1978; but in 1979, 60 such carriers ( 40 percent more) operated. Still more airlines opened for business, until the number peaked at 87 in $1984{ }^{40}$
The established major airlines successfully regained market share by means of the following changes:

- Flying more routes
- Making cooperative arrangements with commuter airlines to offer more continuous routes under the same brand name so as to offer greater convenience and more visibility
- Using computer reservation systems tied in with travel agencies and offering a range of prices for the same trip
- Conducting frequent-flyer programs
- Increasing production quotas of personnel

The number of carriers decreased to 60 in 1989 as mainly the newer ones failed. The number of carriers then climbed to 96 by $1996^{41}$ as demand for travel continued to increase and the successful strategies of the majors had already had their most crucial effects. ${ }^{42}$

Yet the level of competition has been greater ever since deregulation because, since 1978, the major carriers have competed much more with each other on particular routes. ${ }^{43}$ Surprisingly enough, the number of carriers nationwide shows little relationship to overall prices, the volume of business, or employment. (See chart 3.) But the number of carriers serving a particular route is highly relevant to ticket prices on that route. Naturally, routes served by a larger number of competitors have lower prices per mile. ${ }^{44}$

During regulation, from 1969 to 1978, average per-mile ticket costs, adjusted for inflation using the CPI, fell 2.2 percent per year. After deregulation, real prices fell at only a slightly faster rate, 2.3 percent. (See chart 4.) While the airliner was no longer changing so substantially to produce more economical operations, price competition was occurring. According to one respected source, deregulation was responsible for 58 percent of the price cuts from 1978 to 1993 and made fares 22 percent lower than they would have been without deregulation. ${ }^{45} \mathrm{As}$ stated earlier, lower prices raise demand and contribute to growth and, in turn, employment.

In recent years, however, ticket prices have fallen at a reduced rate. From 1986 to 1998 , they declined by 1.8 percent per year.

## Changed rules and productivity

Labor productivity, highly relevant to the rate of growth in jobs, had already been increasing impressively before deregulation; larger and faster craft made greater productivity on the part of flight crews possible. After 1978, the causes of increasing productivity changed, as management developed responses to the newly competitive environment. In earlier years, the increasing capacity of the average airliner allowed more
passengers to be transported by a flight crew, aided by a dispatcher and other ground personnel whose efforts also became more efficient as the airliner grew. But in the new competitive market, the average capacity of a passenger aircraft (in seats) about leveled off, then dropped by 14 percent from 1986 to 1996. When a price war strained airline budgets soon after deregulation, massive layoffs by certain major airlines, reduced pay, and renegotiated work rules were used to cut costs. ${ }^{46}$ Reservations systems were computerized and shared among airlines, reducing the manual workload entailed in reservations.
The development of the hub-and-spoke system of routes in the early 1980s was especially advantageous. ${ }^{47}$ Instead of the simpler, more traditional arrangement of routes between paired cities, passengers from various points of origin were flown to a "hub" and then grouped together to fill a large craft more fully during a common leg of their journeys. The hub-andspoke system was successful in increasing the number of seats filled. "Load factor," the percentage of passenger seats filled, had increased by 0.2 percent per year from 1958 to 1978, but increased more than three times as fast, by 0.7 percent per year, from 1978 to 1996. The hub-and-spoke system, however, was only one factor responsible for the gains; the deliberate use of smaller aircraft on routes with less demand has been another important cause of increasing load factors. ${ }^{48}$ Despite more frequent use of smaller craft, the average number of passengers carried per aircraft mile increased from 90 in 1978 to 103 in 1996, making craft and crew more productive. ${ }^{49}$

Productivity on a per-employee basis ${ }^{50}$ has shown improvement almost continuously since 1947, increasing every year except 1980, 1981, and 1988 to 1991 (mostly years of recession, when reduced business activity in general worked against load factors). Despite all the benefits of competition, output per employee advanced much more slowly after 1978, when ongoing changes to the aircraft were not so economically meaningful. Gains of 6.4 percent per year from 1958 to 1978 slowed to 2.6 percent per year during the 18 -year period ending in 1996 . Once the hub-and-spoke system and computer reservations systems had already been implemented, the rate of increase in productivity slowed to 1.7 percent per year from 1986 to 1996. The following tabulation summarizes the percent change per year in output per person in air transport.

> Annual rate of change

| 1958-78 | 6.4 |
| :---: | :---: |
| 1968-78 | 4.8 |
| 1978-96 | 2.6 |
| 1978-86 | 3.8 |
| 1986-96 | 1.7 |

Because productivity has been rising more slowly in recent years, requirements for labor have been greater recently than

they would have been if productivity had continued to rise at the faster rates of the past.

The use of smaller planes to reduce costs, while not directly relevant to labor productivity, is also an important means of economizing. Smaller aircraft are used more often to cut costs of equipment and fuel, even if labor productivity is reduced somewhat as a result. Smaller craft often are appropriate for more minor spoke routes. ${ }^{51}$ Most aircraft also are configured with less room per seat to increase the number of seats and the potential revenues of each flight, reducing comfort but contributing to lower prices. ${ }^{52}$

The various means of increasing labor productivity and of increasing the productivity of capital contribute to lower costs that enable the airlines to reduce fares. Lower fares attract more passengers and contribute to growth and employment.

## Safety

Another important long-term trend in the industry, seldom recognized as a contributor to industry growth in recent decades, is airline safety. The increasingly safe nature of commercial flight may be a factor in the public's increased flying. Rates of accidents and fatalities have declined greatly in the long term. ${ }^{53}$

As the possibility of deregulation was debated in the 1970s, critics predicted that the loss of regulation would result in a major decline in safety as smaller, less reliable airlines gained larger shares of traffic and as established carriers were pressured to reduce costs, including aircraft maintenance. ${ }^{54}$ (Only economic regulation was being debated. Regulation for purposes of safety, including required maintenance of craft, specified training of pilots, and right-of-way rules in the sky, was never ended or even seriously considered for termination by any important party.) Trends in two measures of airline safety have remained favorable, although improvements have decelerated.

Passenger fatalities per million aircraft-miles is one established measure of air safety. Accidents per thousand departures may be a better one, though, for measuring the fitness of pilots, controllers, and equipment, considering that the crash of just one large aircraft can skew the fatality statistic. Departures and arrivals are the most hazardous normal operations because they involve the greatest proximity to the ground as well as the heavier traffic of the airport environment. Furthermore, the fatalities-per-miles measure is subject to distortion when the average length of a flight changes, but the rate of accidents per thousand departures is free of influence by the length of flights.

According to both statistical measures of safety, the air transportation system improved both before and after deregulation. Far greater improvement occurred in times closer to the beginning of substantial commercial aviation, because the relatively young industry had more problems to solve. (See chart 5.)

The following tabulation will give an idea of the progress that has been made since 1958, although the year-to-year variability of figures makes precise analysis of progress in safety difficult.

Average annual percent change

| Fatalities | Accidents per |
| :---: | :---: |
| per million | 1,000 |
| aircraft miles | departures |

| $1958-96$ | ......................................................................................................$~$ | -3.7 | -6.1 |
| :--- | ---: | ---: | ---: |
| $1958-78$ | -.3 | -.4 |  |

In 1996, 8.2 million scheduled departures entailed 32 accidents, including three fatal ones. The same year, 319 passengers out of 581 million carried were killed, implying a fatality rate of one death for every 1.8 million people boarded. ${ }^{55}$

Because the most dramatic decreases in accidents occurred in the earlier decades of the period under study, it seems likely that most of the increase in the public's confidence in aviation also occurred during the earlier decades. If greater confidence in the safety of aviation contributes to the growth of business, the bulk of such economic effects were probably also in the earlier decades.

## Analysis

In the last 40 years, in commercial aviation, fares after adjusting for inflation have declined, labor productivity has increased, and output and employment have increased vastly. Such trends appear to suggest continuous driving forces. Certain factors, such as at least some improvement in safety, general economic growth, and increased international trade have endured from the regulatory period to the free-market period and have continued to contribute to the growth of the industry. But by all accounts, great changes in the economics of aviation occurred. The pre-regulatory, regulatory, and postregulatory periods each allowed for certain types of progress in the industry. The development of the airplane itself into a safe, fast, and efficient vehicle, primarily during the pre-regulatory and regulatory periods, allowed vast commercial progress. The development of radio navigation systems and air traffic control, also primarily before deregulation, reduced accidents, probably reducing the public's fear of aviation. Navigation systems and air traffic control also made air service more reliable because flight became sensible in a greater range of weather conditions. After deregulation, competition drove airlines to find ways to economize in operations to lower fares. Recent fares, after adjustment for inflation, are cheaper than ever.

General economic deceleration accounts for only part of the deceleration in the growth of air transport. Other explana-

tions have to do with innovations that contributed to acceleration in growth as they were introduced and as they spread but now have been largely completed. Aircraft ceased to become larger or so radically improved in engine design as when the jet engine first came into commercial use. The time-saving and cost-cutting accomplished by the two major changes to the craft have long ceased to be new advantages over the operations of the recent past. Hub-and-spoke routing and computer reservations systems have become standard in the
industry. They can no longer serve to accelerate growth, as they did when they were introduced and as they spread. The one-time technological and operational innovations of both the regulatory period and the post-regulatory period have been standard for years, and cannot now increase the rate of growth; ticket sales via the Internet are one possible exception. After 1986, increases in productivity, reductions in fares, and the growth of output and employment decelerated. Further innovation may be required if growth is to be as rapid as in the past.

# Comparing earnings inequality using two major surveys 

#### Abstract

Some previous research suggests that discrepancies exist between the National Longitudinal Survey of Youth and the Current Population Survey in terms of earnings trends; when the sample is limited to full-time, year-round workers, however, the discrepancies are largely eliminated

Mark S. Handcock, Martina Morris, and Annette Bernhardt

Mark S. Handcock is a statistician and Martina Morris is a sociologist at Pennsylvania State University, and Annette Bernhardt is a sociologist at the Institute on Education and the Economy, Teachers College, Columbia University

Much of the research on the growing dispersion of earnings has relied on the March supplement to the Current Population Survey (CPS). As the research questions have turned to such issues as job instability and long-term wage growth, however, the focus often has shifted to longitudinal surveys, such as the Panel Study of Income Dynamics (PSID) ${ }^{1}$ and the National Longitudinal Surveys (NLS). ${ }^{2}$ In a recent unpublished but widely cited paper, ${ }^{3}$ Peter Gottschalk and Robert A. Moffitt compare annual earnings trends from the PSID and two cohorts of the NLS with those of the CPS. ${ }^{4}$ The authors find that reported earnings in the PSID and the original NLS cohort show roughly the same trends as the CPS, although the magnitudes are quite different.

For the later NLS cohort, however, known as the National Longitudinal Survey of Youth 1979 (NLSY79), Gottschalk and Moffitt find both significantly lower variance in reported annual earnings and a negative trend in variance over time (1979-1988)-at least for high school graduates. In addition, a more recently published paper using different methodology finds a similar discrepancy. ${ }^{5}$ Because the findings of these studies stand in sharp contrast to the well-known "stylized fact" that the variance in earnings was increasing substantially during the 1980 s, serious questions may be raised about the validity of the NLSY79 for research on the topic of recent trends in earnings inequality.

This article focuses on the comparison be-
tween the NLSY79 and the CPS, updating the Gottschalk-Moffitt analysis to 1994, the final year of data collection for the NLSY79 cohort. Because Gottschalk and Moffitt report few discrepancies in the trends for high school dropouts, the analysis is restricted to high school graduates. The article begins by replicating the GottschalkMoffitt analysis in order to verify the discrepancies in reported earnings between the two sets of data. Next, exploratory data analysis and respecified regression models are used to compare the trends and patterns, and to look for potential sources of the discrepancies. The final section discusses the implications of the findings for the validity of the two samples.

## Data and methods

The present study generally follows the conventions adopted by Gottschalk and Moffitt. For their benchmark analyses, they select white males in the civilian noninstitutionalized population and divide the samples into cells defined by single years of age (from 16 to 31 years), level of education (less than a high school education, high school graduate or more), and survey year (1979-88). ${ }^{6}$ Nominal annual earnings are adjusted for inflation and are expressed in constant (1982) dollars. Also, to avoid topcoding issues and reduce the problem of earnings nominally falling below minimum wage, the top and bottom 5 percent of the values are trimmed out within each cell. Because the trimming is based
on the percentiles within cells rather than across the entire sample, the cells are the unit of analysis. As in the earlier paper, for the regression analyses, the CPS and NLSY79 samples are restricted to respondents who were aged 20 years or older in the survey year and whose earnings and number of weeks worked during the previous calendar year both were positive. The dependent variable is the within-cell standard deviation of trimmed real log annual earnings in the year prior to the interview.

Updating the Gottschalk-Moffitt analysis beyond 1988 requires some changes to the sample selection criteria due to changes in survey coding procedures that have taken place since then. In addition, to focus the sample more tightly on a homogeneous set of white males, some new exclusions are adopted. The following tabulation compares the sample selection criteria used in the present analysis with those used by Gottschalk and Moffitt in their study.

Criteria ................
Years ....................
Age range.............
Race.

Enrollment ...........

Earnings $\qquad$
Regression sample: Age ................... Weeks worked ..

Gottschalk-Moffitt
1979-1988
16-21 in 1979
White

Employment status recode-based exclusion
Positive

20 years and older Positive

Updated analysis
1979-1994
16-21 in 1979
White, nonHispanic

No student exclusion
Positive

20 years and older Positive

The most important difference in the criteria used here concerns the exclusion of students. On the basis of the "employment status recode" variable, Gottschalk and Moffitt exclude CPS and NLSY79 respondents who reported school attendance as their major activity during the survey week. But the coding for this variable in the CPS was changed in 1988 and it no longer identifies school attendance as a unique status. To preserve consistency across the time series, therefore, this analysis does not directly exclude students in this way. The overall impact of the change is relatively small, though, because several of the other exclusions (positive earnings and number of weeks worked, for example) capture much of the same population.?

For each data set, descriptive regression analyses similar to those used in the earlier study were conducted to compare the trends in earnings across the different samples. Let $y_{a t}$ be the standard deviation of the log annual wages for workers age $a$ in year $t$. The model fit by Gottschalk and Moffitt is a simple linear specification:
$y_{a t}=\beta_{0}+\beta_{1} a+\beta_{2} t+\varepsilon_{a t} \quad a=20, \ldots, 36 ; t=79, \ldots, 94$
where $\beta_{1}$ and $\beta_{2}$ are the coefficients for the linear effects of age and year, respectively. The present analysis extends the earlier study in two ways. First, the regression model is respecified and two alternative specifications are examined: a nonparametric model for the age term and a random-effects model to capture the longitudinal sample dependence in the NLSY79.

The regression residuals for model A show a marked curvilinear pattern in age that is roughly parabolic in nature. The time trend is of primary interest here, rather than the effects of age. Given the correlation between year and age in these samples, however, the age effect must be specified properly to obtain an accurate estimate of the time trend. As the linear age specification compromises the interpretation and statistical significance of the coefficients of both linear coefficients, the model is respecified using a nonparametric age effect, as follows:
$y_{a t}=\alpha_{e}+\beta_{a}+\beta t+\varepsilon_{a t} \quad a=20, \ldots, 36 ; t=79, \ldots, 94$
where $\beta_{0}, \ldots, \beta_{36}$ are coefficients for each age and $\beta$ is the regression parameter for the linear time trend.

It is important to note that the two previous studies have treated both the CPS and the NLSY79 as cross-sectional surveys, although the latter is a longitudinal survey. There are eight cohorts in the NLSY79, defined by respondent's age in 1979, and each cohort is followed across the entire 16 years of the series. Observations from the same cohort in the NLSY79 are likely to be correlated across time, a fact not taken into account in the Gottschalk-Moffitt analysis, the study by Thomas MaCurdy and others (cited earlier), or in the models (A and B) shown above. The cohort sample dependence can be modeled in one of two ways-as a fixed effect or as a random effect. Adding a fixed effect to either model A or model B is not possible because the parameters for age, year, and cohort are perfectly confounded (cohort = year minus age). A random-effect specification is therefore required and also is more appropriate from a substantive standpoint. The interest here is not in the cohort effects as indicators of inherent differences among specific age-year groups. The cohorts are simply samples from their populations, and this study seeks to capture the covariance in these samples over time, rather than an estimate of a cohort-specific level effect. Therefore, model B is respecified for the NLSY79 to include a random effect for cohort, as follows:
$y_{\text {atc }}=\alpha+\beta_{a}+\beta t+\varepsilon_{t c} \quad a=20, \ldots, 36 ; t=79, \ldots, 94 ;$
$c=1, \ldots, 8$;
$\varepsilon_{i c}=\phi_{c}+\sigma_{t c}$
where $\beta_{20}, \ldots, \beta t_{36}$ are coefficients for each age, $\beta$ is the coeffi-
cient for the linear effect of year, and $\phi_{I}, \ldots, \phi_{g}$ are random variance components for each cohort. Because it requires no assumptions about the parametric form of the random cohort effects, a generalized estimating equation (GEE) is used to fit the model. ${ }^{8}$

For all of the linear models, weights are used to reflect the differing variances of the $y_{a t}$ component of the model. ${ }^{9}$ In the GEE models, the variance-covariance weight matrix includes covariance estimates in the offdiagonal cells to adjust for the longitudinal cohort sample dependence. All models are fit using the S-PLUS statistical program. ${ }^{10}$

The second way in which the present study extends the Gottschalk-Moffitt analysis is by reexamining the discrepancies in earnings dispersion by labor force status. Gottschalk and Moffitt use several indicators as proxies of labor force attachment in an attempt to explain the discrepancy in earnings trends: the employment status recode variable, more than 40 weeks worked in the past year, and age 23 years and older (presumably to exclude most collegeage students). The present study takes a more direct approach, subdividing the sample into two groups: full-time, year-round workers (FTFY) and others (non-FTFY). The FTFY group comprises those who worked 35 or more hours per week and 50 or more weeks per year during the previous calendar year; the non-FTFY group comprises those who had positive earnings and hours worked but who did not work work full time and year round. For the CPS, the constructed variable that identifies this status is used, and for the NLSY79, hours and weeks are selected directly. The definition is the same in both samples. The idea here, as in the earlier study, is to compare workers with relatively strong attachments to the labor force with workers who are less attached to the labor force.

## Results

Tables 1 and 2 provide summary statistics for labor force attachment and annual earnings for workers in both data sets in 1979, the first year of the series. The sample selections reflect the updated analysis criteria and can be compared with the corresponding tables in the paper by Gottschalk and Moffitt. Table 2 shows patterns similar to those found in the earlier study-a significantly larger portion of the NLSY79 sample reports working 40 weeks or more per year. While fairly pronounced in 1979, this discrepancy in the number of weeks worked during the year declines in subsequent years.

Despite the difference in reported number of weeks worked, the earnings figures in table 2 are quite similar across the two samples. There are no systematic differences in either means or variances. The numerical values are different than those reported by Gottschalk and Moffitt, due largely to the inclusion here of students who had been excluded in the earlier study on the basis of the employment status recode variable. The bottom portion of the table shows the statistics for FTFY respondentsa group likely to exclude such students-and here the two samples become very close.

The trends in earnings variances over time for the two samples are shown in chart 1 . They show a general decrease in earnings dispersion with age, and this pattern is much stronger than the trend over time within specific age groups. The NLSY79 estimates are more variable, reflecting the smaller sample sizes. Net of the differences in variability between the two samples, the greatest differences between them occur within the younger age groups-those aged 19 to 24 years. These differences are not very systematic, and in particular, they do not appear to take the form of consistently stronger increasing trends over time in the CPS. There is some conver-

Note: Statistics are calculated using sample weights and 5 percent trim of top and bottom earnings. Unweighted $N$ reflects post-trim cell values.
gence between the two samples for the older respondents, but the earnings dispersion for the nLsY79 is about 10 percent lower, on average, than for the CPS. By contrast, the cell median incomes in the NLSY79 are consistently about 20 percent higher than the corresponding CPS cell means (data not shown here). Once the two samples of respondents settle into their prime working years, then, the annual earnings reported in the NLSY79 are both higher and less variable than those reported in the CPS.
The standard deviations are modeled by reverting to cells defined by survey year and single year of age. Much like the Gottschalk-Moffitt study, attention here is restricted to those aged 20 years and older, with positive weeks worked in the previous calendar year. The results are displayed in table 3. All coefficients are multiplied by 10 to be consistent with the values reported by Gottschalk and Moffitt. The coefficients can be interpreted as the change in standard deviation over a 10 -year period.
The results obtained by Gottschalk and Moffitt are shown in the first three rows of the table for comparison. Consider first their results based on the employment status recode schooling exclusion. For the CPS, they find a positive but not significant upward trend in earnings dispersion, while the corresponding trend for the NLSY79 is negative and also not significant. Using a more specific measure of school enrollment over the past year that is available in the NLSY79 to exclude students in that sample, they find the coefficient for the trend in dispersion changes sign and becomes as strongly positive as it had been negative, though still not significant. Further restricting this NLSY79 sample to those aged 23 years and older, they find the coefficient changes sign again and is
now much more strongly negative than it had been, though still not significant.

The Gottschalk-Moffitt estimate of the time trend is thus extremely sensitive to the sample exclusions. The same is true in the present analysis, in part due to the relatively small number of observations in each cell after the screens for positive earnings and weeks worked and the 10 -percent trimming. This makes for a high level of instability in the cell-specific estimates of the earnings variance, and these in turn have a large impact on the within-age trend estimates. The latter is due to the interaction between the model, which estimates the time trend within age, and the structure of the sample. While the two surveys cover 16 years, age groups are observed for, at most, 8 years, and the average for persons aged 20 years and older is 6.3 years. The moving cohort window is thus not an ideal structure for capturing trends within age over time. When drawing inferences about the discrepancies between the two samples, it should be kept in mind that the estimates are not particularly robust.
The remaining rows in table 3 present the results from the updated analysis. In the first set, we restrict the sample to the years used by Gottschalk and Moffitt, 1979-1988. The differences between the results for model A and the results in the first row of the Gottschalk-Moffitt figures reflect the difference in the sample restrictions between the two analyses-namely, the inclusion in this analysis of students who were excluded from the earlier study on the basis of the CPS employment status recode, as well as the exclusion here of Hispanics. The impacts are not dramatic, with the CPS coefficient becoming slightly less positive under the new sample restrictions. The NLSY79 coefficient becomes more

NOTE: Respondents are grouped in 2-year intervals. Bars show the 95-percent confidence intervals.
negative and now also is statistically significant, though in magnitude it still lies within the range of estimates reported in the earlier study.
When a nonparametric specification for age is adopted in model B, the discrepancy declines-the CPS coefficient increases modestly, and the NLSY79 coefficient becomes much less negative. When the random effect for the longitudinal cohort dependence in the NLSY79 (model C) is added, the coefficient for the time trend again becomes slightly less negative, and now it is about 30 percent lower than the initial estimate in model A. While the numerical results obtained in the earlier study are not replicated exactly, the general pattern is replicated, showing an increasing trend for earnings dispersion in the CPS and a decreasing trend for the NLSY79. The magnitude of the discrepancy and of the negative trend in the NLSY79 becomes smaller in both of the respecified models.
The next set of results shown in table 3 (labeled all workers) updates the analysis to 1994. For the CPS, the trend in earnings dispersion is now significantly negative in model A, as is the trend for the NLSY79. With the nonparametric age effect, the sign of the CPS coefficient changes to become positive (although weakly so and not significant), while the magnitude of the NLSY79 coefficient is still negative but reduced by about half. Adding the random effect to the NLSY79 slightly increases the magnitude of the negative trend, but it is still 40 percent lower than the estimate under the initial model. Respecifying the model once again reduced the discrepancy between the two samples.
The results from model C are graphically displayed in chart 2 . The top panel plots the nonparametric age-effect estimates. The results show that earnings dispersion is highest among the young, and it falls steeply through the midtwenties age groups. For the CPS, dispersion then begins to rise slightly, while for the NLSY79, the decline continues through the early-thirties age groups, though less steeply, and then also begins to rise. The nonlinearity for the CPS is more pronounced, which helps to explain why the nonparametric specification in Model B has a relatively larger impact on the trend coefficient for that sample.
The bottom panel of chart 2 shows the partial regression plot of earnings dispersion by year after adjusting for age. The trend lines are nonparametric local-linear estimates. As can be seen, the CPS trend is modestly positive. The plot for the NLSY79, by contrast, clearly shows a negative trend. Note, however, the large residual variation. The magnitudes of the time trends for both samples are modest relative to the residual variability.
Next, the analysis is restricted to full-time, year-round workers in order to determine whether the discrepancies in earnings dispersion between the two samples persist among the core group of workers with the strongest attachment to

Note: Model A specifies linear effects for both age and year, model B specifies a non-parametric age effect, and Model C includes a random effect for longitudinal cohort dependence in the NLSY79.
the labor force. This group becomes an increasingly larger share of the two samples over time, rising from about 35 percent of the regression-eligible sample in 1979 to 80 percent in 1994. If the trend differential persists for these workers, then it is a fundamental and pervasive discrepancy. If not, then the samples are comparable for the core workers, and some progress has been made in narrowing down the possible sources of the problem.

The trend coefficient under model A reproduces the discrepancy observed above, but the negative trend for the NLSY79 is substantially smaller than in all of the previous analyses. The estimates from model B are consistent with the earlier pat-tern-that is, the discrepancy narrows as the trend becomes more positive for the CPS and less negative for the NLSY79. When the random effect for the sample dependence in model C is added, however, the NLSY79 coefficient changes sign, becoming strongly positive and similar in magnitude to the CPS coefficient, though not statistically significant. Under model C,
then, both samples of full-time, year-round workers show a positive trend in earnings dispersion of comparable magnitude.

The results for the other (non-FTFY) workers show the opposite pattern, with the discrepancy very large under model A and virtually unchanged under model C. For these workers, opposite trends are seen in earnings dispersion for the two samples-dispersion grows over time in the CPS, while it declines over time in the NLSY79. The pattern of statistical significance is also different for this subgroup, with the NLSY79 trends testing highly significant and the CPS trends testing only modestly significant.

The age effects and partial regression plots for model C for the full-time, year-round workers and for the other workers are shown in chart 3. The pattern of higher dispersion for older NLSY79 respondents also is visible here in both subgroups. The smoothed trend lines are clearly different, however, with the FTFY workers in both the CPS and NLSY79 samples now showing a weak positive trend. The residual variability also differs: it is now lower for the FTFY workers and higher for the non-FTFY workers. The smoothed trend lines do not tell an entirely unambiguous story-when the endpoints are excluded, a different trend sometimes emerges. The regression line would be even more strongly influenced by the high leverage points at the extremes, simply reinforcing the earlier point that caution is appropriate when drawing inferences from any of the trend coefficients estimated from these samples.

One final analysis was conducted in which the self-employed were excluded. This is a group known to have highly variable earnings. They are almost universally excluded in studies of earnings inequality because their earnings determination process is fundamentally different from that of wage and salary workers. Excluding the self-employed, the pattern obtained is basically the same as that of the full sample of FTFY workers: in the final specification of model C, both samples again show a positive trend of similar magnitude in earnings dispersion over time.

These analyses suggest that the earnings dispersion discrepancy found by Gottschalk and Moffitt results largely from the specification of their regression model as well as a trend that appears to be driven by workers who do not work full time and year round. To examine the latter, chart 4 shows the trends in earnings dispersion by age-year cell separately for FTFY and non-FTFY workers. ${ }^{11}$ The trends for FTFY workers look similar for the two samples-that is, both groups show a modest upward trend. The age effects discussed earlier (see chart 1) are completely absent here. In the graph for nonFTFY workers, by contrast, the CPS shows a fairly stable pattern of earnings dispersion over time, while the trend for the NLSY79 is somewhat negative. This clearly is what is driving the negative trend in the NLSY79 data when both groups of workers are combined. For non-FTFY workers, the age differ-
ences are absent as well. Thus, what at first appears to be an age effect in the graph for all workers actually is a composition ef-fect-as age increases, the majority of workers shift from nonFTFY status to working full time and year round.

To better understand the nature of these discrepancies, it is useful to look at estimates of the distributions themselves. Chart 5 shows the 1979 earnings densities for the two samples as an example. ${ }^{12}$ The top panel corresponds to all workers. While the two distributions are similar at the higher earnings levels, the CPS sample has a longer, denser lower tail than the NLSY79 sample. The bottom panel shows the corresponding distributions for non-FTFY workers. The CPS distribution is strongly downshifted, indicating lower levels of reported earnings compared with the NLSY79, and the bottom tail of the distribution for these workers reaches much further down the earnings scale. The location of the lower tail of the non-FTFY earnings density, from about 6 to 8 on the log scale, corresponds exactly to the location of the lower tail differences in the distribution for all workers. The plot for FTFY workers, not shown here, looks much like the plot for all workers, without the greater relative density in the lower tail of the CPS.

This lower tail discrepancy becomes more pronounced over time, as can be seen by the $90: 50$ and $50: 10$ earnings ratios for non-FTFY workers shown in chart 6 . The 50:10 ratio for the two samples is relatively similar at the start of the series, but the CPS ratio increases over time while the NLSY79 ratio declines. Given the consistently lower median reported earnings in the CPS, the rise in the 50:10 ratio implies an increasingly longer tail at the bottom of the distribution than that observed in the NLSY79. The 90:50 ratios are more similar for the two samples, with both showing a downward trend over time, though the timing of the decline is different. The variance differential between the two samples is thus being driven primarily by the discrepancies in the lower tails. Specifically, it is being driven by the longer lower tail of the CPS non-FTFY earnings distribution.

## Discussion

The discrepant findings in the trends in annual earnings dispersion between the CPS and the NLSY79 appear to be a function of the model specification and the non-FTFY workers. Regression diagnostics clearly show that a linear specification for age is not appropriate, and fitting a nonparametric effect reduces the discrepancy in the estimated dispersion trends by one-third to one-half. Treating the two samples as cross-sectional, thus ignoring the longitudinal cohort dependence in the NLSY79, also is not appropriate. Modeling the cohort dependence in the NLSY79 changes the estimates of the dispersion trend, especially when the sample is restricted to FTFY workers.

Chart 2. Estimated age effects, regression results under model C

NOTE: Regression results are for both full-time, full-year and non-full-time, -full-year workers. Trend shown as a local linear smoothed estimate.

Part-time or part-year workers

Chart 5. Annual earnings density estimates, 1979

Chart 6. Trends in the 90:50 and 50:10 annual earnings ratios, 1979-94

After these corrections, the earnings dispersion trends for FTFY workers look remarkably similar for the two samples. Formal analysis confirms this visual impression-the estimated trends in earnings dispersion are nearly identical. Thus, restricting the samples to FTFY workers, no significant discrepancy in earnings variance is found between the two data sets: both the CPS and NLSY79 show a general trend of increasing earnings dispersion over time.

The trends in earnings dispersion among non-FTFY workers, however, appear to be different in the two samples. Closer examination of the two earnings distributions shows clearly that the distribution of reported annual earnings among nonFTFY workers in the CPS is both strongly downshifted and skewed more to the left than in the NLSY79. CPS respondents who do not work full time and year round not only report lower earnings, on average, but also the bottom tail of their distribution reaches much farther down the earnings scale. These differences already are pronounced in 1979, and they grow over time, thus contributing directly to the growing discrepancy between the two samples.

For both groups of workers, annual earnings reports are higher in the NLSY79 than in the CPS by about 20 percent at the median. This begins to suggest that the primary source of the discrepancy may be underreporting in the CPS. The most likely explanation is differences in the respective questionnaires, because neither sample bias nor attrition bias has been suggested as a problem in the NLSY79. ${ }^{13}$ As noted in the study by Gottschalk and Moffitt, the design of the NLSY79 questionnaire probably increases the accuracy of earnings reports. The sequence of questions asked about individual jobs in the NLSY79 aids in the recall of both earnings and hours relative to the CPS, and the effect would be expected to be strongest for part-time or part-year workers with irregular schedules and sources of earnings.

In addition, the NLSY79 is administered as a face-to-face interview, whereas the CPS, except for the initial interview, usually is administered by telephone. ${ }^{14}$ This probably will raise the validity and reliability of the NLSY79 data relative to the CPS. The longitudinal basis of the NLSY79 provides a continuing relationship between the respondents and the survey organization. The promise of confidentiality has been met over time, and respondents may feel more comfortable disclos-
ing sensitive information on earnings. Also, in the CPS, proxy reports may be a factor. All of this suggests that the discrepancies in non-FTFY annual earnings reports between the CPS and the NLSY79 may be due to underreporting in the CPS.

It is worth reiterating, however, that the regression trend estimates obtained from these samples should be interpreted with care. They were found to be highly sensitive to small changes in sample selection and model specification. The structure of the analytic question, which focuses analysis on the trends within age over time, leads to both relatively small cell sizes for estimating dispersion, and a mismatch between sample structure and the analytic task. To obtain stable estimates of the time trend, one would need relatively long periods of observation within age groups. The cohort scheme of the NLSY79, with its 8 -year moving age window over time, only provides a maximum of 8 years during which any respondents are observed at a particular age, and some of the age segments include less than 2 years of observation. ${ }^{15}$ Of course, the equivalent CPS sample reflects the same constraints. While the goal of benchmarking the NLSY79 against the CPS is an important one, the NLSY79 sample structure is not ideal for answering the question posed here, and it is not clear that the survey would ever be used in this fashion.

With that caveat, however, the findings described in this article still attest to the validity of the NLSY79 data. Researchers should therefore take advantage of these data to examine the longitudinal questions for which this survey was designed. In general, the National Longitudinal Surveys, with their unique employer identification codes, remain the only longitudinal data set with an accurate measure of job and employer stability-a significant feature, given the many contradictory empirical findings in this field. ${ }^{16}$ The age range covered by the survey provides a detailed window into the period when roughly two-thirds of lifetime job changes and wage growth occur. ${ }^{17}$ These also are the formative years of labor market experience when long-term relationships with employers are established. The two National Longitudinal Survey cohorts also bracket the growth in earnings inequality that emerged in the 1980s. Together, the cohorts of the National Longitudinal Surveys provide a unique resource for the analysis of these and other important economic and social issues covering the last 30 years.

## Notes

[^8]in 1990 to almost 8,700 in 1995. As of 1995, the PSID had collected information about more than 50,000 individuals spanning as much as 28 years of their lives. For more information on the PSID, visit their website at http://www.isr.umich.edu/src/psid/.
${ }^{2}$ The National Longitudinal Surveys (NLS), sponsored and directed by the Bureau of Labor Statistics, gather detailed information about the labor market experiences and other aspects of the lives of six groups of men and women. Over the years, a variety of other government agencies, such as the National Institute of Child Health and Human Development, the Department
of Defense, and the Department of Education, the Department of Justice, the National Institute on Drug Abuse, and the National School to Work Office, have funded components of the surveys that provided data relevant to their missions. As a result, the surveys include data about a wide range of events such as schooling and career transitions, marriage and fertility, training investments, child-care usage, and drug and alcohol use. The depth and breadth of each survey allow for analysis of an expansive variety of topics such as the transition from school to work, job mobility, youth unemployment, educational attainment and the returns to education, welfare recipiency, the impact of training, and retirement decisions.

The first set of surveys, initiated in 1966, consisted of four cohorts. These four groups are referred to as the "older men," "mature women," "young men," and "young women" cohorts of the NLS, and are known collectively as the "original cohorts." In 1979, a longitudinal study of a cohort of young men and women aged 14 to 22 was begun. This sample of youth was called the National Longitudinal Survey of Youth 1979 (NLSY79). In 1986, the NLSY79 was expanded to include surveys of the children born to women in that cohort, with the new cohort called the NLSY79 Children. In 1997, the NLS program was again expanded with a new cohort of young people aged 12 to 16 as of December 31, 1996. This new cohort is the National Longitudinal Survey of Youth 1997 (NLSY97).

The National Longitudinal Surveys, especially the NLSY79, have exceptional retention rates. As a result, many nLS survey members have been followed for many years, some for decades, allowing researchers to study large panels of men, women, and children over significant segments of their lives. For more information on the National Longitudinal Surveys, see the NLS Handbook, 1999 (Bureau of Labor Statistics, 1999).
${ }^{3}$ See Peter Gottschalk and Robert A. Moffitt, "Changes in the structure of earnings in three longitudinal data sets," 1997, unpublished.
${ }^{4}$ The Current Population Survey (CPS), which uses a scientifically selected sample of about 50,000 households, is conducted monthly for the Bureau of Labor Statistics by the Bureau of the Census. The CPS provides statistics on the labor force status of the civilian noninstitutional population of the United States, aged 16 years of older. In the CPS, respondents are asked about their activity during the week that includes the 12th day of the month, the so-called reference week. As such, the CPS is a cross-sectional survey of the population, as opposed to a longitudinal survey like the NLS. For more information on the CPS, see BLS Handbook of Methods, Bulletin 2490 (Bureau of Labor Statistics, April 1997), pp. 4-14.
${ }^{5}$ See Thomas MaCurdy, Thomas Mroz, and R. Mark Gritz, "An Evaluation of the National Longitudinal Survey of Youth," Journal of Human Resources, Spring 1998, pp. 345-436.
${ }^{6}$ To further minimize heterogeneity, this study excludes Hispanics from the samples analyzed. The study by Gottschalk and Moffitt made no such exclusion.
${ }^{7}$ For the regression-eligible sample used here, ESR-type students represent about 15 percent of the respondents in 1979, dropping to 5 percent in 1985 and down to 1 percent by 1988.
${ }^{8}$ See Peter J. Diggle, Kung-Yee Liang, and Scott L. Zeger, Analysis of Longitudinal Data, (New York, Oxford University Press), 1994.
${ }^{9}$ See Gottschalk and Moffitt, "Changes in the structure of earnings," p. 7.

10 s-PLUS is an enhanced version of the $S$ environment for data analysis. Unix and Windows versions are available from MathSoft, Inc. The programs used for the analysis in this paper are available from the authors.
${ }^{11}$ As in Chart 1, 2-year age groups are used. For FTFY workers, the values average about 180 respondents per cell for the NLSY79 and about 870 respondents per cell for the CPS. For non-FTFY workers, the corresponding values average about 90 and 300 , respectively.
${ }^{12}$ For this figure ages within a year are pooled, but the distributions have been compositionally adjusted for the differences in marginal age distributions between the CPS and NLSY79.
${ }^{13}$ See MaCurdy and others, "An Evaluation of the National Longitudinal Survey of Youth."
${ }^{14}$ In the cPS, respondents are part of the survey for 4 consecutive months, then they are out of the survey for the following 8 months, and finally they are back in the survey for 4 more months the following year. The first interviews are supposed to take place in person, at the home of the respondents, although face-to-face interviews are not always possible. In any case, subsequent interviews are conducted by telephone.
${ }^{15}$ Ages 20 to 29 provide 8 years of observation each, other ages in the 16 -to- 36 year range provide 8 minus the difference to the closer of the two endpoints. In the analysis by Gottschalk and Moffitt, which only included up to survey year 1988, only three ages ( 20 to 23 ) would have provided 8 years of observation; all others would have provided fewer years of observation.

${ }^{17}$ See Kevin Murphy and Finnis Welch, "Empirical Age-Earnings Profiles," Journal of Labor Economics, April 1990, pp. 202-29; and Robert Topel and Michael Ward, "Job Mobility and the Careers of Young Men," Quarterly Journal of Economics, May 1992, pp. 439-79.

## Précis

## Telecommuting or work invasion?

Telecommuting-using the Internet and other communications technologies to enable significant regular work at sites away from a traditional workplace-remains the wave of the future, according to some observers. An article by Federal Computer Week reporters Colleen O'Hara and Natasha Haubold finds that telecommuting among Federal workers has leveled off at about 25,000 workers in 1999, well short of an informal goal of 60,000 telecommuters. O'Hara and Haubold report that such factors as management attitude, data security, and technical support are some of the challenges restraining the growth of these work arrangements in the Federal sector.

A Stanford University study, Internet and Society: A Preliminary Report, of the impact of the Internet also finds little evidence that telecommuting is starting to make strong inroads. Although the principal author, Professor Norman H. Nie, expressed some surprise at the degree to which survey respondents reported using the Internet at home to do work for an employer, the report found that only a small number ( 4 percent) had reduced hours at a regular worksite while increasing hours worked at home. In fact, according to the study, "more than a quarter of full- or part-time workers who use the Internet more than 5 hours a week said that the Internet has increased the amount of time working at home without decreasing the amount of time working in the office."

Some of the language used in the Stanford report was also indicative of other attitudinal challenges telecommuters might face. The chart of the work data is labeled "Chart 8: Work invades home and increases at the office," and the text of an accompanying press release echoes the theme. After admitting the possibility that the 4 percent of Internet users who have cut back on hours at the office may be the start of telecommuting, Nie is quoted as saying: "On the other hand, we all know
from our cell phones and laptops that work appears to be intruding into every other aspect of our lives, and that's one of the clearest trends in these data."

## Computer-aided instruction

A witticism attributed to Robert Solow holds that, "We can see the computer age everywhere but in the productivity statistics." There is widespread agreement that this paradox is a measurement problemofficial price and output data are simply missing the computer revolution.

Every now and then, however, a shadow of doubt appears. Are computers truly an unalloyed boon for productivity? One recent example takes the form of a study, New Evidence on Classroom Computers and Pupil Learning, a NBER working paper by Joshua Angrist and Victor Lavy.

Their paper analyzes the impact of Israel's "Tomorrow-98" program, an ambitious effort to upgrade the computer resources available to elementary and middle schools in that nation. If one accepts average pupil test scores as a measure of output, then the authors' findings that there is "a consistently negative relationship between the program-induced use of computers and fourth-grade math scores" and " $[\mathrm{f}]$ or other grades and subjects, the estimates are not significant, though also mostly negative," are troublesome. Perhaps, the computer revolution is having a beneficial effect everywhere but in the productivity statistics and the productivity of the classroom.

This study, of course, is not, and does not purport to be, a complete productivity analysis. For one thing, there is little information on inputs to be matched with the data on educational outcomes. But Angrist and Lavy conclude by questioning whether those inputs appear to be justified by performance.

## Workplace practices and the New Economy

Much of the discussion of a "New Economy" focuses on information technology - hardware, software, capital expenditures, and so forth. Sandra E. Black and Lisa M. Lynch's recent NBER working paper, What's Driving the New Economy: The Benefits of Workplace Innovation, picks up the parallel argument which some analysts have made that some part of the renaissance in productivity is attributable to "increased managerial focus on quality management, continuous innovation, incentive-based compensation, and employee involvement programs."

Using data from the 1993 and 1996 waves of the Educational Quality of the Workforce NationalEmployers Survey (EQW-NES), Black and Lynch found considerable change in such workplace practice over the 3-year period. Nearly a third of firms in the survey changed in their deployment of benchmarking, number of management levels, and share of workers in self-managed teams or other regular councils. Black and Lynch found that the diffusion of technology, as measured by change in the proportion of nonmanagers using computers, is positively related to productivity. The authors also concluded that workplace practices matter: " $[F]$ irms that re-engineer their workplace to incorporate more high performance practices experience higher productivity growth. Profitsharing and/or stock options are also associated with higher productivity growth, although it is not always statistically significant in all specifications. ... Finally, employee voice (as proxied by the percentage of workers meeting regularly to discuss workplace issues) does appear to contribute to labor productivity."

# Lessons from the Depression 

The Economics of the Great Depression. Edited by Mark Wheeler. Kalamazoo, mI, w.e. Upjohn Institute for Employment Research, 1998, 211 pp .

What do people know about the causes of the Great Depression? We certainly know that the era altered the lives of everyone who experienced it, but it is difficult to recognize how bad those times were in comparison to more recent periods. Certainly unemployment was high and there were dramatic efforts to improve the economy in the 1930s, but what policy lessons can be learned to help us avoid or recover from such tremendous economic shocks in the future? Politicians, economists, and writers have studied these issues for decades, but what insights do modern economists have to share on the topic?

The Economics of the Great Depression is a collection of academic papers discussing what happened and what we can learn from the Great Depression. The six authors provide a mix of approaches and views into the causes of the event, and their differing interpretations of data, events, and policies reflect a wide range of economic thinking. Some of the essays are historically ori-ented-what happened and what was thought at the time; others relate to the present situation-what actions were taken and what policy lessons are useful for today. The authors used investment analyses, econometric methods, and review of public microdata records to address the subject. The arguments offered are concise and thought provoking, although they are couched in the technical jargon of the economist.

As might be expected, there was a range of analytical approaches to the issue. One historical study looked at characteristics of the unemployment and those who were unemployed during the Great Depression. Unemploy-
ment episodes during the Depression were much longer than previously and many episodes lasted for more than a year. As well, those who were unemployed for these long periods tended to be either younger workers or older workers, and workers with fewer skills and less education. Another essay noted that the severity of the Depression varied by industry and region in the United States, and even among countries. Although aggregate output and employment declined, there were increases in both output and employment for some consumer industries. Further, the Depression was less severe in Southern States than in some other parts of the country such as in the Northwest and the Central States. As well, the decrease in international trade forced many lessdeveloped countries to shift emphasis away from raw-material exports and toward industrialization for internal consumption. Thus, the Great Depression affected different areas in different ways.

Some of the papers examined the root causes of the Great Depression. One economist analyzed a number of theories that sought to explain the length and severity of the Depression, such as collapse of the financial markets, government and Federal Reserve policies, and economic maturation. Another used econometric modeling to test a number of possible causes, although it determined no dominant explanation. A study by David C. Wheelock examined the impact of policies developed during the Great Depression on more recent actions of the Federal Reserve. He specifically cited the impact of 1930s changes to currency requirements that led to a Federal Reserve bias toward inflationary monetary policies in the 1960s and 1970s.

Economist Stephen Cecchetti proposed that deflation, itself a result of the significant economic downturn, explained several other behaviors and effects of the Great Depression. Deflation decreased the value of real goods and especially hurt those who were heavily in-
vested in such goods, including factory owners, landowners (such as farmers) and lenders (such as banks). It also led to a desire to maintain assets in cash, leading to bank runs and cash hoarding. Cecchetti suggested a key lesson from the Great Depression is that deflation leads to such catastropic consequences that policymakers should avoid it at all costs.

It is no surprise that there was no firm agreement as to the reasons for the Great Depression among these six economists. Further, because of the technical language, this book is no casual read. Nonetheless, it increases the economic understanding of the Great Depression and its causes. It rigorously examines various explanations for the Depression, shows weaknesses in the simple answers often given for it, and provides some policy lessons for the future. Thus, it is a worthwhile addition to the vast literature concerning the Great Depression.

## Income inequality

Income Inequality in America: An Analysis of Trends. By Paul Ryscavage. Armonk, NY, M.E. Sharpe, Inc., 1998, 229 pp. $\$ 56.95$, hardcover; $\$ 22.95$, paperback.

With the U.S. economy approaching the longest uninterrupted expansion on record, unemployment and inflation at their lowest levels in decades, and real earnings growing after years of stagnation, it may seem an odd time to write a book about income inequality in America. Yet, despite rosy economic conditions overall, not all Americans are riding the current wave of economic prosperity. Millions remain in poverty. Constant restructuring in the U.S.
economy has displaced many workers from "middle class" jobs once considered secure, and some workers must settle for contingent jobs, which by definition may not be there for them tomorrow.

Against this setting, Paul Ryscavage (who formerly worked for both the Bureau of Labor Statistics and the Bureau of the Census) has written Income Inequality in America. It is accurately billed as a primer on income inequality. The book is well-written, readily understandable, and comprehensive. It provides an overview of the data, tools, and techniques used to gauge income inequality and a thorough assessment of income inequality trends in the United States. The book includes a discussion of some of the latest thinking on the underlying causes behind the growing earnings and income inequality of recent decades, and also compares the U.S. experience with that of other industrialized nations.
Ryscavage recognizes at the very outset of his book that the topic is "provocative." The subject provokes controversy among economists because even though there is a general consen-
sus that the distribution of income in America has become more polarized in recent decades, there is comparatively little agreement on the answers to questions that naturally follow. How much has income inequality grown? Is it still growing? What are the underlying causes? If growing income inequality is a bad thing, as is widely assumed, what are the policy prescriptions that can reverse the trend? In his book, Ryscavage sifts through the data and the literature to provide some answers to the first three questions, but deliberately steers clear of the much more politicallycharged debate over the merits and limitations of various policies designed to address growing income inequality.

The subject is also provocative, if not overtly so, for many "main street" Americans-persons who have not studied the issue but have nevertheless sensed that something is happening to the distribution of income in the country. They see it when the local shoe factory closes or when the bulldozers turn the family farm down the road into an expensive housing development. Their perception is fueled further by news sto-
ries recounting the enormous pay packages awarded to business executives and professional sport figures, juxtaposed with daily announcements of mass layoffs. Unfortunately, laypersons attempting to square their perceptions of income inequality-commonly thought of in terms of the declining middle class-with actual facts and figures may be discouraged by complicated and sometimes contradictory stories on the topic. Getting a fix on the "truth" is made even more difficult by the polemical tone that pervades much of the discussion.

Income Inequality in America does a good job of summarizing what is known, as well as what is not known, about income inequality. Perhaps most importantly, the information is presented in an apolitical, unbiased manner. Although the subject matter is technical by nature, persons with a nontechnical background also can learn from this book. It is a good resource for anyone interested in studying the issue.

## Notes on Current Labor Statistics

This section of the Review presents the principal statistical series collected and calculated by the Bureau of Labor Statistics: series on labor force; employment; unemployment; labor compensation; consumer, producer, and international prices; productivity; international comparisons; and injury and illness statistics. In the notes that follow, the data in each group of tables are briefly described; key definitions are given; notes on the data are set forth; and sources of additional information are cited.

## General notes

The following notes apply to several tables in this section:

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect on the data of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might prevent short-term evaluation of the statistical series. Tables containing data that have been adjusted are identified as "seasonally adjusted." (All other data are not seasonally adjusted.) Seasonal effects are estimated on the basis of past experience. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years.

Seasonally adjusted data appear in tables $1-14,16-17,39$, and 43 . Seasonally adjusted labor force data in tables 1 and 4-9 were revised in the February 1999 issue of the Review. Seasonally adjusted establishment survey data shown in tables $1,12-14$ and 1617 were revised in the July 1998 Review and reflect the experience through March 1998. A brief explanation of the seasonal adjustment methodology appears in "Notes on the data."

Revisions in the productivity data in table 45 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month-to-month and quarter-to-quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average AllItems CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data-such as the "real" earnings shown in table 14 -are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current-dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100 . For example, given a current hourly wage rate of $\$ 3$ and a current price
index number of 150 , where $1982=100$, the hourly rate expressed in 1982 dollars is $\$ 2$ $(\$ 3 / 150 \times 100=\$ 2$ ). The $\$ 2$ (or any other resulting values) are described as "real," "constant," or "1982" dollars.

## Sources of information

Data that supplement the tables in this section are published by the Bureau in a variety of sources. Definitions of each series and notes on the data are contained in later sections of these Notes describing each set of data. For detailed descriptions of each data series, see BLS Handbook of Methods, Bulletin 2490. Users also may wish to consult Major Programs of the Bureau of Labor Statistics, Report 919. News releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule appearing on the back cover of this issue.

More information about labor force, employment, and unemployment data and the household and establishment surveys underlying the data are available in the Bureau's monthly publication, Employment and Earnings. Historical unadjusted and seasonally adjusted data from the household survey are available on the Internet:
http://stats.bls.gov/cpshome.htm
Historically comparable unadjusted and seasonally adjusted data from the establishment survey also are available on the Internet:
http://stats.bls.gov/ceshome.htm Additional information on labor force data for areas below the national level are provided in the BLS annual report, Geographic Profile of Employment and Unemployment.

For a comprehensive discussion of the Employment Cost Index, see Employment Cost Indexes and Levels, 1975-95, BLS Bulletin 2466. The most recent data from the Employee Benefits Survey appear in the following Bureau of Labor Statistics bulletins: Employee Benefits in Medium and Large Firms; Employee Benefits in Small Private Establishments; and Employee Benefits in State and Local Governments.

More detailed data on consumer and producer prices are published in the monthly periodicals, The CPI Detailed Report and Producer Price Indexes. For an overview of the 1998 revision of the CPI, see the December 1996 issue of the Monthly Labor Review. Additional data on international prices appear in monthly news releases.

Listings of industries for which productivity indexes are available may be found on the Internet:
http://stats.bls.gov/iprhome.htm
For additional information on interna-
tional comparisons data, see International Comparisons of Unemployment, BLS Bulletin 1979.

Detailed data on the occupational injury and illness series are published in Occupational Injuries and Illnesses in the United States, by Industry, a BLS annual bulletin.

Finally, the Monthly Labor Review carries analytical articles on annual and longer term developments in labor force, employment, and unemployment; employee compensation and collective bargaining; prices; productivity; international comparisons; and injury and illness data.

## Symbols

n.e.c. $=$ not elsewhere classified.
n.e.s. $=$ not elsewhere specified.
$\mathrm{p}=$ preliminary. To increase the timeliness of some series, preliminary figures are issued based on representative but incomplete returns.
$\mathrm{r}=$ revised. Generally, this revision reflects the availability of later data, but also may reflect other adjustments.

## Comparative Indicators

## (Tables 1-3)

Comparative indicators tables provide an overview and comparison of major BLS statistical series. Consequently, although many of the included series are available monthly, all measures in these comparative tables are presented quarterly and annually.

Labor market indicators include employment measures from two major surveys and information on rates of change in compensation provided by the Employment Cost Index (ECI) program. The labor force participation rate, the employment-to-population ratio, and unemployment rates for major demographic groups based on the Current Population ("household") Survey are presented, while measures of employment and average weekly hours by major industry sector are given using nonfarm payroll data. The Employment Cost Index (compensation), by major sector and by bargaining status, is chosen from a variety of BLS compensation and wage measures because it provides a comprehensive measure of employer costs for hiring labor, not just outlays for wages, and it is not affected by employment shifts among occupations and industries.

Data on changes in compensation, prices, and productivity are presented in table 2.

Measures of rates of change of compensation and wages from the Employment Cost Index program are provided for all civilian nonfarm workers (excluding Federal and household workers) and for all private nonfarm workers. Measures of changes in consumer prices for all urban consumers; producer prices by stage of processing; overall prices by stage of processing; and overall export and import price indexes are given. Measures of productivity (output per hour of all persons) are provided for major sectors.

Alternative measures of wage and compensation rates of change, which reflect the overall trend in labor costs, are summarized in table 3. Differences in concepts and scope, related to the specific purposes of the series, contribute to the variation in changes among the individual measures.

## Notes on the data

Definitions of each series and notes on the data are contained in later sections of these notes describing each set of data.

## Employment and Unemployment Data

(Tables 1; 4-20)

## Household survey data

## Description of the series

Employment data in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 50,000 households selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

## Definitions

Employed persons include (1) all those who worked for pay any time during the week which includes the 12 th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the pre-
ceding 4 weeks. Persons who did not look for work because they were on layoff are also counted among the unemployed. The unemployment rate represents the number unemployed as a percent of the civilian labor force.

The civilian labor force consists of all employed or unemployed persons in the civilian noninstitutional population. Persons not in the labor force are those not classified as employed or unemployed. This group includes discouraged workers, defined as persons who want and are available for a job and who have looked for work sometime in the past 12 months (or since the end of their last job if they held one within the past 12 months), but are not currently looking, because they believe there are no jobs available or there are none for which they would qualify. The civilian noninstitutional population comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy. The civilian labor force participation rate is the proportion of the civilian noninstitutional population that is in the labor force. The employment-population ratio is employment as a percent of the civilian noninstitutional population.

## Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the intercensal years. These adjustments affect the comparability of historical data. A description of these adjustments and their effect on the various data series appears in the Explanatory Notes of Employment and Earnings.

Labor force data in tables 1 and 4-9 are seasonally adjusted. Since January 1980, national labor force data have been seasonally adjusted with a procedure called X-11 ARIMA which was developed at Statistics Canada as an extension of the standard X11 method previously used by BLS. A detailed description of the procedure appears in the X-11 arima Seasonal Adjustment Method, by Estela Bee Dagum (Statistics Canada, Catalogue No. 12-564E, January 1983).

At the beginning of each calendar year, historical seasonally adjusted data usually are revised, and projected seasonal adjustment factors are calculated for use during the January-June period. The historical seasonally adjusted data usually are revised for only the most recent 5 years. In July, new seasonal adjustment factors, which incorporate the experience through June, are produced for the July-December period, but no revisions are made in the historical data.

## Revisions in the household survey

Data beginning in 1999 are not strictly comparable with data for 1998 and earlier years because of the introduction of revised population controls. Additional information appears in the February 1999 issue of Employment and Earnings.

FOR ADDITIONAL INFORMATION on national household survey data, contact the Division of Labor Force Statistics: (202) 691-6378.

## Establishment survey data

## Description of the series

Employment, hours, and earnings data in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by about 390,000 establishments representing all industries except agriculture. Industries are classified in accordance with the 1987 Standard Industrial Classification (SIC) Manual. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

## Definitions

An establishment is an economic unit which produces goods or services (such as a factory or store) at a single location and is engaged in one type of economic activity.

Employed persons are all persons who received pay (including holiday and sick pay) for any part of the payroll period including the 12 th day of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in manufacturing include working supervisors and nonsupervisory workers closely associated with production operations. Those workers mentioned in tables 11-16 include production workers in manufacturing and mining;
construction workers in construction; and nonsupervisory workers in the following industries: transportation and public utilities; wholesale and retail trade; finance, insurance, and real estate; and services. These groups account for about four-fifths of the total employment on private nonagricultural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. Real earnings are earnings adjusted to reflect the effects of changes in consumer prices. The deflator for this series is derived from the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W).

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received, and are different from standard or scheduled hours. Overtime hours represent the portion of average weekly hours which was in excess of regular hours and for which overtime premiums were paid.

The Diffusion Index represents the percent of industries in which employment was rising over the indicated period, plus one-half of the industries with unchanged employment; 50 percent indicates an equal balance between industries with increasing and decreasing employment. In line with Bureau practice, data for the 1-, 3-, and 6-month spans are seasonally adjusted, while those for the 12 -month span are unadjusted. Data are centered within the span. Table 17 provides an index on private nonfarm employment based on 356 industries, and a manufacturing index based on 139 industries. These indexes are useful for measuring the dispersion of economic gains or losses and are also economic indicators.

## Notes on the data

Establishment survey data are annually adjusted to comprehensive counts of employment (called "benchmarks"). The latest adjustment, which incorporated March 1997 benchmarks, was made with the release of May 1998 data, published in the July 1998 issue of the Review. Coincident with the benchmark adjustment, historical seasonally adjusted data were revised to reflect updated seasonal factors and refinement in the seasonal adjustment procedures. Unadjusted data from April 1997 forward and seasonally adjusted data from January 1994 forward are subject to revision in future benchmarks.

Revisions in State data (table 11) occurred with the publication of January 1999 data.

Beginning in June 1996, the BLS uses the X-12 ARIMA methodology to seasonally adjust establishment survey data. This procedure, developed by the Bureau of the Census, controls for the effect of varying survey
intervals (also known as the 4 versus 5-week effect), thereby providing improved measurement of over-the-month changes and underlying economic trends. Revisions of data, usually for the most recent 5 -year period, are made once a year coincident with the benchmark revisions.

In the establishment survey, estimates for the most recent 2 months are based on incomplete returns and are published as preliminary in the tables (12-17 in the Review). When all returns have been received, the estimates are revised and published as "final" (prior to any benchmark revisions) in the third month of their appearance. Thus, December data are published as preliminary in January and February and as final in March. For the same reasons, quarterly establishment data (table 1) are preliminary for the first 2 months of publication and final in the third month. Thus, fourth-quarter data are published as preliminary in January and February and as final in March.

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," Monthly Labor Review, December 1969, pp. 9-20.

For additional information on establishment survey data, contact the Division of Monthly Industry Employment Statistics: (202) 691-6555.

## Unemployment data by State

## Description of the series

Data presented in this section are obtained from the Local Area Unemployment Statistics (LAUS) program, which is conducted in cooperation with State employment security agencies.

Monthly estimates of the labor force, employment, and unemployment for States and sub-State areas are a key indicator of local economic conditions, and form the basis for determining the eligibility of an area for benefits under Federal economic assistance programs such as the Job Training Partnership Act. Seasonally adjusted unemployment rates are presented in table 10. Insofar as possible, the concepts and definitions underlying these data are those used in the national estimates obtained from the CPS.

## Notes on the data

Data refer to State of residence. Monthly data for all States and the District of Columbia are derived using standardized procedures established by BLS. Once a year, estimates are revised to new population controls, usually with publication of January estimates, and benchmarked to annual average CPS levels.

FOR ADDITIONAL INFORMATION on data in this series, call (202) 691-6392 (table 10) or (202) 691-6559 (table 11).

## Compensation and Wage Data

## (Tables 1-3; 21-27)

COMPENSATION AND WAGE dATA are gathered by the Bureau from business establishments, State and local governments, labor unions, collective bargaining agreements on file with the Bureau, and secondary sources.

## Employment Cost Index

## Description of the series

The Employment Cost Index (ECI) is a quarterly measure of the rate of change in compensation per hour worked and includes wages, salaries, and employer costs of employee benefits. It uses a fixed market basket of labor-similar in concept to the Consumer Price Index's fixed market basket of goods and services-to measure change over time in employer costs of employing labor.

Statistical series on total compensation costs, on wages and salaries, and on benefit costs are available for private nonfarm workers excluding proprietors, the self-employed, and household workers. The total compensation costs and wages and salaries series are also available for State and local government workers and for the civilian nonfarm economy, which consists of private industry and State and local government workers combined. Federal workers are excluded.

The Employment Cost Index probability sample consists of about 4,400 private nonfarm establishments providing about 23,000 occupational observations and 1,000 State and local government establishments providing 6,000 occupational observations selected to represent total employment in each sector. On average, each reporting unit provides wage and compensation information on five well-specified occupations. Data are collected each quarter for the pay period including the 12th day of March, June, September, and December.

Beginning with June 1986 data, fixed employment weights from the 1980 Census of Population are used each quarter to calculate the civilian and private indexes and the index for State and local governments. (Prior to June 1986, the employment weights are from the 1970 Census of Population.) These fixed weights, also used to derive all of the industry and occupation series indexes, ensure that changes in these indexes reflect only changes in compensa-
tion, not employment shifts among industries or occupations with different levels of wages and compensation. For the bargaining status, region, and metropolitan/nonmetropolitan area series, however, employment data by industry and occupation are not available from the census. Instead, the 1980 employment weights are reallocated within these series each quarter based on the current sample. Therefore, these indexes are not strictly comparable to those for the aggregate, industry, and occupation series.

## Definitions

Total compensation costs include wages, salaries, and the employer's costs for employee benefits.

Wages and salaries consist of earnings before payroll deductions, including production bonuses, incentive earnings, commissions, and cost-of-living adjustments.

Benefits include the cost to employers for paid leave, supplemental pay (including nonproduction bonuses), insurance, retirement and savings plans, and legally required benefits (such as Social Security, workers' compensation, and unemployment insurance).

Excluded from wages and salaries and employee benefits are such items as payment-inkind, free room and board, and tips.

## Notes on the data

The Employment Cost Index for changes in wages and salaries in the private nonfarm economy was published beginning in 1975. Changes in total compensation cost-wages and salaries and benefits combined-were published beginning in 1980. The series of changes in wages and salaries and for total compensation in the State and local government sector and in the civilian nonfarm economy (excluding Federal employees) were published beginning in 1981. Historical indexes (June 1981=100) are available on the Internet:
http://stats.bls.gov/ecthome.htm
FOR ADDITIONAL INFORMATION on the Employment Cost Index, contact the Office of Compensation Levels and Trends: (202) 691-6199.

## Employee Benefits Survey

## Description of the series

Employee benefits data are obtained from the Employee Benefits Survey, an annual survey of the incidence and provisions of selected benefits provided by employers. The survey collects data from a sample of approximately 9,000 private sector and State and local government establishments. The
data are presented as a percentage of employees who participate in a certain benefit, or as an average benefit provision (for example, the average number of paid holidays provided to employees per year). Selected data from the survey are presented in table 25 for medium and large private establishments and in table 26 for small private establishments and State and local government.

The survey covers paid leave benefits such as holidays and vacations, and personal, funeral, jury duty, military, family, and sick leave; short-term disability, long-term disability, and life insurance; medical, dental, and vision care plans; defined benefit and defined contribution plans; flexible benefits plans; reimbursement accounts; and unpaid family leave.

Also, data are tabulated on the incidence of several other benefits, such as severance pay, child-care assistance, wellness programs, and employee assistance programs.

## Definitions

Employer-provided benefits are benefits that are financed either wholly or partly by the employer. They may be sponsored by a union or other third party, as long as there is some employer financing. However, some benefits that are fully paid for by the employee also are included. For example, longterm care insurance and postretirement life insurance paid entirely by the employee are included because the guarantee of insurability and availability at group premium rates are considered a benefit.

Participants are workers who are covered by a benefit, whether or not they use that benefit. If the benefit plan is financed wholly by employers and requires employees to complete a minimum length of service for eligibility, the workers are considered participants whether or not they have met the requirement. If workers are required to contribute towards the cost of a plan, they are considered participants only if they elect the plan and agree to make the required contributions.

Defined benefit pension plans use predetermined formulas to calculate a retirement benefit (if any), and obligate the employer to provide those benefits. Benefits are generally based on salary, years of service, or both.

Defined contribution plans generally specify the level of employer and employee contributions to a plan, but not the formula for determining eventual benefits. Instead, individual accounts are set up for participants, and benefits are based on amounts credited to these accounts.

Tax-deferred savings plans are a type of defined contribution plan that allow participants to contribute a portion of their salary to an employer-sponsored plan and defer in-
come taxes until withdrawal.
Flexible benefit plans allow employees to choose among several benefits, such as life insurance, medical care, and vacation days, and among several levels of coverage within a given benefit.

## Notes on the data

Surveys of employees in medium and large establishments conducted over the 1979-86 period included establishments that employed at least 50,100 , or 250 workers, depending on the industry (most service industries were excluded). The survey conducted in 1987 covered only State and local governments with 50 or more employees. The surveys conducted in 1988 and 1989 included medium and large establishments with 100 workers or more in private industries. All surveys conducted over the 1979-89 period excluded establishments in Alaska and Hawaii, as well as part-time employees.

Beginning in 1990, surveys of State and local governments and small private establishments were conducted in evennumbered years, and surveys of medium and large establishments were conducted in oddnumbered years. The small establishment survey includes all private nonfarm establishments with fewer than 100 workers, while the State and local government survey includes all governments, regardless of the number of workers. All three surveys include full- and part-time workers, and workers in all 50 States and the District of Columbia.

For additional information on the Employee Benefits Survey, contact the Office of Compensation Levels and Trends on the Internet:
http://stats.bls.gov/ebshome.htm

## Work stoppages

## Description of the series

Data on work stoppages measure the number and duration of major strikes or lockouts (involving 1,000 workers or more) occurring during the month (or year), the number of workers involved, and the amount of work time lost because of stoppage. These data are presented in table 27.

Data are largely from a variety of published sources and cover only establishments directly involved in a stoppage. They do not measure the indirect or secondary effect of stoppages on other establishments whose employees are idle owing to material shortages or lack of service.

## Definitions

Number of stoppages: The number of strikes and lockouts involving 1,000 work-
ers or more and lasting a full shift or longer.
Workers involved: The number of workers directly involved in the stoppage.

Number of days idle: The aggregate number of workdays lost by workers involved in the stoppages.

Days of idleness as a percent of estimated working time: Aggregate workdays lost as a percent of the aggregate number of standard workdays in the period multiplied by total employment in the period.

## Notes on the data

This series is not comparable with the one terminated in 1981 that covered strikes involving six workers or more.

FOR ADDITIONAL INFORMATION on work stoppages data, contact the Office of Compensation and Working Conditions: (202) 691-6282, or the Internet: http://stats.bls.gov/cbahome.htm

## Price Data

(Tables 2; 28-38)
Price data are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base pe-riod-1982 = 100 for many Producer Price Indexes, 1982-84 = 100 for many Consumer Price Indexes (unless otherwise noted), and $1990=100$ for International Price Indexes.

## Consumer Price Indexes

## Description of the series

The Consumer Price Index (CPI) is a measure of the average change in the prices paid by urban consumers for a fixed market basket of goods and services. The CPI is calculated monthly for two population groups, one consisting only of urban households whose primary source of income is derived from the employment of wage earners and clerical workers, and the other consisting of all urban households. The wage earner index (CPIw) is a continuation of the historic index that was introduced well over a half-century ago for use in wage negotiations. As new uses were developed for the CPI in recent years, the need for a broader and more representative index became apparent. The all-urban consumer index (CPI-U), introduced in 1978, is representative of the 1993-95 buying habits of about 87 percent of the noninstitutional population of the United States at that time, compared with 32 percent represented in the CPI-w. In addition to wage earners and clerical workers, the CPI-U covers professional, managerial, and technical workers, the selfemployed, short-term workers, the unem-
ployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctors' and dentists' fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items are kept essentially unchanged between major revisions so that only price changes will be measured. All taxes directly associated with the purchase and use of items are included in the index.

Data collected from more than 23,000 retail establishments and 5,800 housing units in 87 urban areas across the country are used to develop the "U.S. city average." Separate estimates for 14 major urban centers are presented in table 29. The areas listed are as indicated in footnote 1 to the table. The area indexes measure only the average change in prices for each area since the base period, and do not indicate differences in the level of prices among cities.

## Notes on the data

In January 1983, the Bureau changed the way in which homeownership costs are meaured for the CPI-U. A rental equivalence method replaced the asset-price approach to homeownership costs for that series. In January 1985, the same change was made in the CPI-w. The central purpose of the change was to separate shelter costs from the investment component of home-ownership so that the index would reflect only the cost of shelter services provided by owneroccupied homes. An updated CPI-U and CPIw were introduced with release of the January 1987 and January 1998 data.

FOR ADDITIONAL INFORMATION on consumer prices, contact the Division of Consumer Prices and Price Indexes: (202) 691-7000.

## Producer Price Indexes

## Description of the series

Producer Price Indexes (PPI) measure average changes in prices received by domestic producers of commodities in all stages of processing. The sample used for calculating these indexes currently contains about 3,200 commodities and about 80,000 quotations per month, selected to represent the movement of prices of all commodities produced in the manufacturing; agriculture, forestry, and fishing; mining; and gas and electricity and public utilities sectors. The stage-of-processing structure of PPI organizes products by class of buyer and degree of fabrication (that is, finished goods, intermediate goods, and crude materials). The traditional commodity structure of PPI organizes products by similarity of end use or
material composition. The industry and product structure of PPI organizes data in accordance with the Standard Industrial Classification (SIC) and the product code extension of the SIC developed by the U.S. Bureau of the Census.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13 th day of the month.

Since January 1992, price changes for the various commodities have been averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1987. The detailed data are aggregated to obtain indexes for stage-of-processing groupings, commodity groupings, durability-of-product groupings, and a number of special composite groups. All Producer Price Index data are subject to revision 4 months after original publication.

FOR ADDITIONAL INFORMATION on producer prices, contact the Division of Industrial Prices and Price Indexes: (202) 691-7705.

## International Price Indexes

## Description of the series

The International Price Program produces monthly and quarterly export and import price indexes for nonmilitary goods traded between the United States and the rest of the world. The export price index provides a measure of price change for all products sold by U.S. residents to foreign buyers. ("Residents" is defined as in the national income accounts; it includes corporations, businesses, and individuals, but does not require the organizations to be U.S. owned nor the individuals to have U.S. citizenship.) The import price index provides a measure of price change for goods purchased from other countries by U.S. residents.

The product universe for both the import and export indexes includes raw materials, agricultural products, semifinished manufactures, and finished manufactures, including both capital and consumer goods. Price data for these items are collected primarily by mail questionnaire. In nearly all cases, the data are collected directly from the exporter or importer, although in a few cases, prices are obtained from other sources.

To the extent possible, the data gathered refer to prices at the U.S. border for exports
and at either the foreign border or the U.S. border for imports. For nearly all products, the prices refer to transactions completed during the first week of the month. Survey respondents are asked to indicate all discounts, allowances, and rebates applicable to the reported prices, so that the price used in the calculation of the indexes is the actual price for which the product was bought or sold.

In addition to general indexes of prices for U.S. exports and imports, indexes are also published for detailed product categories of exports and imports. These categories are defined according to the five-digit level of detail for the Bureau of Economic Analysis End-use Classification (SITC), and the fourdigit level of detail for the Harmonized System. Aggregate import indexes by country or region of origin are also available.

BLS publishes indexes for selected categories of internationally traded services, calculated on an international basis and on a bal-ance-of-payments basis.

## Notes on the data

The export and import price indexes are weighted indexes of the Laspeyres type. Price relatives are assigned equal importance within each harmonized group and are then aggregated to the higher level. The values assigned to each weight category are based on trade value figures compiled by the Bureau of the Census. The trade weights currently used to compute both indexes relate to 1990.

Because a price index depends on the same items being priced from period to period, it is necessary to recognize when a product's specifications or terms of transaction have been modified. For this reason, the Bureau's questionnaire requests detailed descriptions of the physical and functional characteristics of the products being priced, as well as information on the number of units bought or sold, discounts, credit terms, packaging, class of buyer or seller, and so forth. When there are changes in either the specifications or terms of transaction of a product, the dollar value of each change is deleted from the total price change to obtain the "pure" change. Once this value is determined, a linking procedure is employed which allows for the continued repricing of the item.

For the export price indexes, the preferred pricing is f.a.s. (free alongside ship) U.S. port of exportation. When firms report export prices f.o.b. (free on board), production point information is collected which enables the Bureau to calculate a shipment cost to the port of exportation. An attempt is made to collect two prices for imports. The first is the import price f.o.b. at the foreign port of exportation, which is consistent with the basis for valuation of imports in the national accounts. The second is the import price c.i.f.(costs, insur-
ance, and freight) at the U.S. port of importation, which also includes the other costs associated with bringing the product to the U.S. border. It does not, however, include duty charges. For a given product, only one price basis series is used in the construction of an index.

FOR ADDITIONAL INFORMATION on international prices, contact the Division of International Prices: (202) 691-7155.

## Productivity Data

(Tables 2; 39-42)

## Business sector and major sectors

## Description of the series

The productivity measures relate real output to real input. As such, they encompass a family of measures which include single-factor input measures, such as output per hour, output per unit of labor input, or output per unit of capital input, as well as measures of multifactor productivity (output per unit of combined labor and capital inputs). The Bureau indexes show the change in output relative to changes in the various inputs. The measures cover the business, nonfarm business, manufacturing, and nonfinancial corporate sectors.

Corresponding indexes of hourly compensation, unit labor costs, unit nonlabor payments, and prices are also provided.

## Definitions

Output per hour of all persons (labor productivity) is the quantity of goods and services produced per hour of labor input. Output per unit of capital services (capital productivity) is the quantity of goods and services produced per unit of capital services input. Multifactor productivity is the quantity of goods and services produced per combined inputs. For private business and private nonfarm business, inputs include labor and capital units. For manufacturing, inputs include labor, capital, energy, non-energy materials, and purchased business services.

Compensation per hour is total compensation divided by hours at work. Total compensation equals the wages and salaries of employees plus employers' contributions for social insurance and private benefit plans, plus an estimate of these payments for the self-employed (except for nonfinancial corporations in which there are no self-employed). Real compensation per hour is compensation per hour deflated by the change in the Consumer Price Index for All Urban Consumers.

Unit labor costs are the labor compensation costs expended in the production of a unit of output and are derived by dividing compensation by output. Unit nonlabor payments include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from current-dollar value of output and dividing by output.

Unit nonlabor costs contain all the components of unit nonlabor payments except unit profits.

Unit profits include corporate profits with inventory valuation and capital consumption adjustments per unit of output.

Hours of all persons are the total hours at work of payroll workers, self-employed persons, and unpaid family workers.

Labor inputs are hours of all persons adjusted for the effects of changes in the education and experience of the labor force.

Capital services are the flow of services from the capital stock used in production. It is developed from measures of the net stock of physical assets-equipment, structures, land, and inventories-weighted by rental prices for each type of asset.

Combined units of labor and capital inputs are derived by combining changes in labor and capital input with weights which represent each component's share of total cost. Combined units of labor, capital, energy, materials, and purchased business services are similarly derived by combining changes in each input with weights that represent each input's share of total costs. The indexes for each input and for combined units are based on changing weights which are averages of the shares in the current and preceding year (the Tornquist index-number formula).

## Notes on the data

Business sector output is an annually-weighted index constructed by excluding from real gross domestic product (GDP) the following outputs: general government, nonprofit institutions, paid employees of private households, and the rental value of owner-occupied dwellings. Nonfarm business also excludes farming. Private business and private nonfarm business further exclude government enterprises. The measures are supplied by the U.S. Department of Commerce's Bureau of Economic Analysis. Annual estimates of manufacturing sectoral output are produced by the Bureau of Labor Statistics. Quarterly manufacturing output indexes from the Federal Reserve Board are adjusted to these annual output measures by the BLS. Compensation data are developed from data of the Bureau of Economic Analysis and the Bureau of Labor Statistics. Hours data are developed from data of the Bureau of Labor Statistics.

The productivity and associated cost mea-
sures in tables 39-42 describe the relationship between output in real terms and the labor and capital inputs involved in its production. They show the changes from period to period in the amount of goods and services produced per unit of input.

Although these measures relate output to hours and capital services, they do not measure the contributions of labor, capital, or any other specific factor of production. Rather, they reflect the joint effect of many influences, including changes in technology; shifts in the composition of the labor force; capital investment; level of output; changes in the utilization of capacity, energy, material, and research and development; the organization of production; managerial skill; and characteristics and efforts of the work force.

FOR ADDITIONAL INFORMATION on this productivity series, contact the Division of Productivity Research: (202) 691-5606.

## Industry productivity measures

## Description of the series

The BLS industry productivity data supplement the measures for the business economy and major sectors with annual measures of labor productivity for selected industries at the three- and four-digit levels of the Standard Industrial Classification system. The industry measures differ in methodology and data sources from the productivity measures for the major sectors because the industry measures are developed independently of the National Income and Product Accounts framework used for the major sector measures.

## Definitions

Output per hour is derived by dividing an index of industry output by an index of labor input. For most industries, output indexes are derived from data on the value of industry output adjusted for price change. For the remaining industries, output indexes are derived from data on the physical quantity of production.

The labor input series consist of the hours of all employees (production and nonproduction workers), the hours of all persons (paid employees, partners, proprietors, and unpaid family workers), or the number of employees, depending upon the industry.

## Notes on the data

The industry measures are compiled from data produced by the Bureau of Labor Statistics, the Departments of Commerce, Interior, and Agriculture, the Federal Reserve Board, regulatory agencies, trade associations, and other sources.

For most industries, the productivity
indexes refer to the output per hour of all employees. For some transportation industries, only indexes of output per employee are prepared. For some trade and service industries, indexes of output per hour of all persons (including self-employed) are constructed.

FOR ADDITIONAL INFORMATION on this series, contact the Division of Industry Productivity Studies: (202) 691-5618.

## International Comparisons

(Tables 43-45)

## Labor force and unemployment

## Description of the series

Tables 43 and 44 present comparative measures of the labor force, employment, and un-employment-approximating U.S. con-cepts-for the United States, Canada, Australia, Japan, and several European countries. The unemployment statistics (and, to a lesser extent, employment statistics) published by other industrial countries are not, in most cases, comparable to U.S. unemployment statistics. Therefore, the Bureau adjusts the figures for selected countries, where necessary, for all known major definitional differences. Although precise comparability may not be achieved, these adjusted figures provide a better basis for international comparisons than the figures regularly published by each country.

## Definitions

For the principal U.S. definitions of the labor force, employment, and unemployment, see the Notes section on Employment and Unemployment Data: Household survey data.

## Notes on the data

The adjusted statistics have been adapted to the age at which compulsory schooling ends in each country, rather than to the U.S. standard of 16 years of age and older. Therefore, the adjusted statistics relate to the population aged 16 and older in France, Sweden, and the United Kingdom; 15 and older in Canada, Australia, Japan, Germany, Italy from 1993 onward, and the Netherlands; and 14 and older in Italy prior to 1993. The institutional population is included in the denominator of the labor force participation rates and employment-population ratios for Japan and Germany; it is excluded for the United States and the other countries.

In the U.S. labor force survey, persons on layoff who are awaiting recall to their jobs are classified as unemployed. European and Japanese layoff practices are quite different in nature from those in the United States; therefore, strict application of the U.S. definition has not been made on this point. For further information, see Monthly Labor Review, December 1981, pp. 8-11.

The figures for one or more recent years for France, Germany, Italy, the Netherlands, and the United Kingdom are calculated using adjustment factors based on labor force surveys for earlier years and are considered preliminary. The recent-year measures for these countries, therefore, are subject to revision whenever data from more current labor force surveys become available.

There are breaks in the data series for the United States (1990, 1994, 1997, 1998), France (1992), Italy (1991, 1993), the Netherlands (1988), and Sweden (1987).

For the United States, the break in series reflects a major redesign of the labor force survey questionnaire and collection methodology introduced in January 1994. Revised population estimates based on the 1990 census, adjusted for the estimated undercount, also were incorporated. In 1996, previously published data for the 1990-93 period were revised to reflect the 1990 census-based population controls, adjusted for the undercount. In 1997, revised population controls were introduced into the household survey. Therefore, the data are not strictly conparable with prior years. In 1998, new composite estimation procedures and minor revisions in population controls were introduced into the household survey. Therefore, the data are not strictly comparable with data for 1997 and earlier years. See the Notes section on Employment and Unemployment Data of this Review.

For France, the 1992 break reflects the substitution of standardized European Union Statistical Office (EUROSTAT) unemployment statistics for the unemployment data estimated according to the International Labor Office (ILO) definition and published in the Organization for Economic Cooperation and Development (OECD) annual yearbook and quarterly update. This change was made because the EUROSTAT data are more up-to-date than the OECD figures. Also, since 1992, the eurostat definitions are closer to the U.S. definitions than they were in prior years. The impact of this revision was to lower the unemployment rate by 0.1 percentage point in 1992 and 1993, by 0.4 percentage point in 1994, and 0.5 percentage point in 1995.

For Italy, the 1991 break reflects a revision in the method of weighting sample data. The impact was to increase the unemployment rate by approximately 0.3 percentage point, from 6.6 to 6.9 percent in 1991.

In October 1992, the survey methodology was revised and the definition of unemployment was changed to include only those who were actively looking for a job within the 30 days preceding the survey and who were available for work. In addition, the lower age limit for the labor force was raised from 14 to 15 years. (Prior to these changes, BLS adjusted Italy's published unemployment rate downward by excluding from the unemployed those persons who had not actively sought work in the past 30 days.) The break in the series also reflects the incorporation of the 1991 population census results. The impact of these changes was to raise Italy's adjusted unemployment rate by approximately 1.2 percentage points, from 8.3 to 9.5 percent in fourth-quarter 1992. These changes did not affect employment significantly, except in 1993. Estimates by the Italian Statistical Office indicate that employment declined by about 3 percent in 1993, rather than the nearly 4 percent indicated by the data shown in table 44. This difference is attributable mainly to the incorporation of the 1991 population benchmarks in the 1993 data. Data for earlier years have not been adjusted to incorporate the 1991 census results.

For the Netherlands, a new survey questionnaire was introduced in 1992 that allowed for a closer application of ILO guidelines. EUROSTAT has revised the Dutch series back to 1988 based on the 1992 changes. The 1988 revised unemployment rate is 7.6 percent; the previous estimate for the same year was 9.3 percent.

There have been two breaks in series in the Swedish labor force survey, in 1987 and 1993. Adjustments have been made for the 1993 break back to 1987. In 1987, a new questionnaire was introduced. Questions regarding current availability were added and the period of active workseeking was reduced from 60 days to 4 weeks. These changes lowered Sweden's 1987 unemployment rate by 0.4 percentage point, from 2.3 to 1.9 percent. In 1993, the measurement period for the labor force survey was changed to represent all 52 weeks of the year rather than one week each month and a new adjustment for population totals was introduced. The impact was to raise the unemployment rate by approximately 0.5 percentage point, from 7.6 to 8.1 percent. Statistics Sweden revised its labor force survey data for 1987-92 to take into account the break in 1993. The adjustment raised the Swedish unemployment rate by 0.2 percentage point in 1987 and gradually rose to 0.5 percentage point in 1992.

Beginning with 1987, BLS has adjusted the Swedish data to classify students who also sought work as unemployed. The impact of this change was to increase the adjusted unemployment rate by 0.1 percentage point
in 1987 and by 1.8 percentage points in 1994, when unemployment was higher. In 1998, the adjusted unemployment rate had risen from 6.5 to 8.4 percent due to the adjustment to include students.

The net effect of the 1987 and 1993 changes and the BLS adjustment for students seeking work lowered Sweden's 1987 unemployment rate from 2.3 to 2.2 percent.

FOR ADDITIONAL INFORMATION on this series, contact the Division of Foreign Labor Statistics: (202) 691-5654.

## Manufacturing productivity and labor costs

## Description of the series

Table 45 presents comparative indexes of manufacturing labor productivity (output per hour), output, total hours, compensation per hour, and unit labor costs for the United States, Canada, Japan, and nine European countries. These measures are trend compari-sons-that is, series that measure changes over time-rather than level comparisons. There are greater technical problems in comparing the levels of manufacturing output among countries.

BLS constructs the comparative indexes from three basic aggregate measures-output, total labor hours, and total compensation. The hours and compensation measures refer to all employed persons (wage and salary earners plus self-employed persons and unpaid family workers) in the United States, Canada, Japan, France, Germany, Norway, and Sweden, and to all employees (wage and salary earners) in the other countries.

## Definitions

Output, in general, refers to value added in manufacturing from the national accounts of each country. However, the output series for Japan prior to 1970 is an index of industrial production, and the national accounts measures for the United Kingdom are essentially identical to their indexes of industrial production.

The 1977-97 output data for the United States are the gross product originating (value added) measures prepared by the Bureau of Economic Analysis of the U.S. Department of Commerce. Comparable manufacturing output data currently are not available prior to 1977.
U.S. gross product originating is a chaintype annual-weighted series. (For more information on the U.S. measure, see Robert E. Yuskavage, "Improved Estimates of Gross Product by Industry, 1959-94," Survey of Current Business, August 1996, pp. 133-55.) The Japanese value added series is based upon one set of fixed price weights for the
years 1970 through 1997. Output series for the other foreign economies also employ fixed price weights, but the weights are updated periodically (for example, every 5 or 10 years).

To preserve the comparability of the U.S. measures with those for other economies, BLS uses gross product originating in manufacturing for the United States for these comparative measures. The gross product originating series differs from the manufacturing output series that BLS publishes in its news releases on quarterly measures of U.S. productivity and costs (and that underlies the measures that appear in tables 39 and 41 in this section). The quarterly measures are on a "sectoral output" basis, rather than a valueadded basis. Sectoral output is gross output less intrasector transactions.

Total labor hours refers to hours worked in all countries. The measures are developed from statistics of manufacturing employment and average hours. The series used for France (from 1970 forward), Norway, and Sweden are official series published with the national accounts. Where official total hours series are not available, the measures are developed by BLS using employment figures published with the national accounts, or other comprehensive employment series, and estimates of annual hours worked. For Germany, BLS uses estimates of average hours worked developed by a research institute connected to the Ministry of Labor for use with the national accounts employment figures. For the other countries, BLS constructs its own estimates of average hours.

Denmark has not published estimates of average hours for 1994-97; therefore, the BLS measure of labor input for Denmark ends in 1993.

Total compensation (labor cost) includes all payments in cash or in-kind made directly to employees plus employer expenditures for legally required insurance programs and contractual and private benefit plans. The measures are from the national accounts of each country, except those for Belgium, which are developed by BLS using statistics on employment, average hours, and hourly compensation. For Canada, France, and Sweden, compensation is increased to account for other significant taxes on payroll or employment. For the United Kingdom, compensation is reduced between 1967 and 1991 to account for em-ployment-related subsidies. Self-employed workers are included in the all-employed-persons measures by assuming that their hourly compensation is equal to the average for wage and salary employees.

## Notes on the data

In general, the measures relate to total manufacturing as defined by the International Stan-
dard Industrial Classification. However, the measures for France (for all years) and Italy (beginning 1970) refer to mining and manufacturing less energy-related products, and the measures for Denmark include mining and exclude manufacturing handicrafts from 1960 to 1966.

The measures for recent years may be based on current indicators of manufacturing output (such as industrial production indexes), employment, average hours, and hourly compensation until national accounts and other statistics used for the long-term measures become available.

FOR ADDITIONAL INFORMATION on this series, contact the Division of Foreign Labor Statistics.

## Occupational Injury and IIIness Data

(Tables 46-47)

## Survey of Occupational Injuries and Illinesses

## Description of the series

The Survey of Occupational Injuries and Illnesses collects data from employers about their workers' job-related nonfatal injuries and illnesses. The information that employers provide is based on records that they maintain under the Occupational Safety and Health Act of 1970. Self-employed individuals, farms with fewer than 11 employees, employers regulated by other Federal safety and health laws, and Federal, State, and local government agencies are excluded from the survey.

The survey is a Federal-State cooperative program with an independent sample selected for each participating State. A stratified random sample with a Neyman allocation is selected to represent all private industries in the State. The survey is stratified by Standard Industrial Classification and size of employment.

## Definitions

Under the Occupational Safety and Health Act, employers maintain records of nonfatal work-related injuries and illnesses that involve one or more of the following: loss of consciousness, restriction of work or motion, transfer to another job, or medical treatment other than first aid.

Occupational injury is any injury such as a cut, fracture, sprain, or amputation that results from a work-related event or a single, instantaneous exposure in the work environment.

Occupational illness is an abnormal condition or disorder, other than one resulting from an occupational injury, caused by exposure to factors associated with employment. It includes acute and chronic illnesses or disease which may be caused by inhalation, absorption, ingestion, or direct contact.

Lost workday injuries and illnesses are cases that involve days away from work, or days of restricted work activity, or both.

Lost workdays include the number of workdays (consecutive or not) on which the employee was either away from work or at work in some restricted capacity, or both, because of an occupational injury or illness. BLS measures of the number and incidence rate of lost workdays were discontinued beginning with the 1993 survey. The number of days away from work or days of restricted work activity does not include the day of injury or onset of illness or any days on which the employee would not have worked, such as a Federal holiday, even though able to work.

Incidence rates are computed as the number of injuries and/or illnesses or lost work days per 100 full-time workers.

## Notes on the data

The definitions of occupational injuries and illnesses are from Recordkeeping Guidelines for Occupational Injuries and Illnesses (U.S. Department of Labor, Bureau of Labor Statistics, September 1986).

Estimates are made for industries and employment size classes for total recordable cases, lost workday cases, days away from work cases, and nonfatal cases without lost workdays. These data also are shown separately for injuries. Illness data are available for seven categories: occupational skin diseases or disorders, dust diseases of the lungs, respiratory conditions due to toxic agents, poisoning (systemic effects of toxic agents), disorders due to physical agents (other than toxic materials), disorders associated with repeated trauma, and all other occupational illnesses.

The survey continues to measure the number of new work-related illness cases which are recognized, diagnosed, and reported during the year. Some conditions, for example, long-term latent illnesses caused by exposure to carcinogens, often are difficult to relate to the workplace and are not adequately recognized and reported. These long-term latent illnesses are believed to be understated in the survey's illness measure. In contrast, the overwhelming majority of the reported new illnesses are those which are easier to directly relate to workplace activity (for example, contact dermatitis and carpal tunnel syndrome).

Most of the estimates are in the form of incidence rates, defined as the number of injuries and illnesses per 100 equivalent fulltime workers. For this purpose, 200,000 em-
ployee hours represent 100 employee years ( 2,000 hours per employee). Full detail on the available measures is presented in the annual bulletin, Occupational Injuries and Illnesses: Counts, Rates, and Characteristics.

Comparable data for more than 40 States and territories are available from the BLS Office of Safety, Health and Working Conditions. Many of these States publish data on State and local government employees in addition to private industry data.

Mining and railroad data are furnished to BLS by the Mine Safety and Health Administration and the Federal Railroad Administration. Data from these organizations are included in both the national and State data published annually.

With the 1992 survey, BLS began publishing details on serious, nonfatal incidents resulting in days away from work. Included are some major characteristics of the injured and ill workers, such as occupation, age, gender, race, and length of service, as well as the circumstances of their injuries and illnesses (nature of the disabling condition, part of body affected, event and exposure, and the source directly producing the condition). In general, these data are available nationwide for detailed industries and for individual States at more aggregated industry levels.

FOR ADDITIONAL INFORMATION on occupational injuries and illnesses, contact the Office of Occupational Safety, Health and Working Conditions at (202) 691-6180, or access the Internet at:
http://www.bls.gov/oshhome.htm

## Census of Fatal Occupational Injuries

The Census of Fatal Occupational Injuries compiles a complete roster of fatal job-related injuries, including detailed data about the fatally injured workers and the fatal events. The program collects and cross checks fatality information from multiple sources, including death certificates, State and Federal workers' compensation reports, Occupational Safety and Health Administration and Mine Safety and Health Administration records, medical examiner and autopsy reports, media accounts, State motor vehicle fatality records, and follow-up questionnaires to employers.

In addition to private wage and salary workers, the self-employed, family members, and Federal, State, and local government workers are covered by the program. To be included in the fatality census, the decedent must have been employed (that is working for pay, compensation, or profit) at the time of the event, engaged in a legal work activity, or present at the site of the incident as a requirement of his or her job.

## Definition

A fatal work injury is any intentional or unintentional wound or damage to the body resulting in death from acute exposure to energy, such as heat or electricity, or kinetic energy from a crash, or from the absence of such essentials as heat or oxygen caused by a specific event or incident or series of events within a single workday or shift. Fatalities that occur during a person's commute to or from work are excluded from the census, as well as work-
related illnesses, which can be difficult to identify due to long latency periods.

## Notes on the data

Twenty-eight data elements are collected, coded, and tabulated in the fatality program, including information about the fatally injured worker, the fatal incident, and the machinery or equipment involved. Summary worker demographic data and event characteristics are included in a national news re-
lease that is available about 8 months after the end of the reference year. The Census of Fatal Occupational Injuries was initiated in 1992 as a joint Federal-State effort. Most States issue summary information at the time of the national news release.

FOR ADDITIONAL INFORMATION on the Census of Fatal Occupational Injuries contact the bls Office of Safety, Health, and Working Conditions at (202) 691-6175, or the Internet at:
http://www.bls.gov/oshhome.htm

## Bureau of Labor Statistics Internet

The Bureau of Labor Statistics World Wide Web site on the Internet contains a range of data on consumer and producer prices, employment and unemployment, occupational compensation, employee benefits, workplace injuries and illnesses, and productivity. The homepage can be accessed using any Web browser:
http://stats.bls.gov.
Also, some data can be accessed through anonymous FTP or Gopher at stats.bls.gov

- Data not available.

NOTE: Figures are the percent of industries with employment increasing plus one-half of the industries with unchanged employment, where 50 percent indicates an equal balance between industries with increasing and
decreasing employment. Data for the 2 most recent months shown in each span are preliminary. See the "Definitions" in this section. See "Notes on the data" for a description of the most recent benchmark revision.

## 18. Annual data: Employment status of the population

' The indexes are calculated differently from those for the occupation and industry groups. For a detailed description of the index calculation, see the Monthly Labor Review Technical Note, "Estimation procedures for the Employment Cost Index," May 1982.
25. Percent of full-time employees participating in employer-provided benefit plans, and in selected features within plans, medium and large private establishments, selected years, 1980-97

The definitions for paid sick leave and short-term disability (previously sickness and accident insurance) were changed for the 1995 survey. Paid sick leave now includes only plans that specify either a maximum number of days per year or unlimited days. Shortterms disability now includes all insured, self-insured, and State-mandated plans available on a per-disability basis, as well as the unfunded per-disability plans previously reported as sick leave. Sickness and accident insurance, reported in years prior to this survey, included only insured, self-insured, and State-mandated plans providing per-disability bene-
fits at less than full pay.
${ }^{2}$ Prior to 1995, reimbursement accounts included premium conversion plans, which specifically allow medical plan participants to pay required plan premiums with pretax dollars. Also, reimbursement accounts that were part of flexible benefit plans were tabulated separately.

NOTE: Dash indicates data not available.
26. Percent of full-time employees participating in employer-provided benefit plans, and in selected features within plans, small private establishments and State and local governments, 1987, 1990, 1992, 1994, and 1996

Methods used to calculate the average number of paid holidays were revised in 1994 to count partial days more precisely. Average holidays for 1994 are not comparable with those reported in 1990 and 1992.
${ }^{2}$ The definitions for paid sick leave and short-term disability (previously sickness and accident insurance) were changed for the 1996 survey. Paid sick leave now includes only plans that specify either a maximum number of days per year or unlimited days. Short-term disability now includes all insured, selfinsured, and State-mandated plans available on a per-disability basis, as well as the unfunded per-disability plans previously reported as
sick leave. Sickness and accident insurance, reported in years prior to this survey, included only insured, self-insured, and State-mandated plans providing per-disability benefits at less than full pay
${ }^{3}$ Prior to 1996, reimbursement accounts included premium conversion plans, which specifically allow medical plan participants to pay required plan premiums with pretax dollars. Also, reimbursement accounts that were part of flexible benefit plans were tabulated separately.

Foods, fuels, and several other items priced every month in all areas; most other goods and services priced as indicated:

## M-Every month.

1-January, March, May, July, September, and November.
2-February, April, June, August, October, and December.
${ }^{2}$ Regions defined as the four Census regions.
${ }^{3}$ Indexes on a December 1996 = 100 base.
${ }^{4}$ The "North Central" region has been renamed the "Midwest" region by the Census Bureau. It is composed of the same geographic entities.
${ }^{5}$ Indexes on a December 1986 = 100 base.
${ }^{6}$ In addition, the following metropolitan areas are published semiannually and appear in tables 34 and 39 of the January and July issues of the CPI Detailed Report: Anchorage, AK; Cincinnati-Hamilton, OH-KY-IN; Denver-Boulder-Greeley, CO; Honolulu, HI; Kansas City,

MO-KS; Milwaukee-Racine, WI; Minneapolis-St. Paul, MN-WI; Pittsburgh, PA; Port-land-Salem, OR-WA; St Louis, MO-IL; San Diego, CA; Tampa-St. Petersburg-Clearwater, FL.
${ }^{7}$ Indexes on a November 1996 = 100 base.

- Data not available.

NOTE: Local area CPI indexes are byproducts of the national CPI program. Each local index has a smaller sample size and is, therefore, subject to substantially more sampling and other measurement error. As a result, local area indexes show greater volatility than the national index, although their long-term trends are similar. Therefore, the Bureau of Labor Statistics strongly urges users to consider adopting the national average CPI for use in their escalator clauses. Index applies to a month as a whole, not to any specific date.

[^26]NOTE: Quarterly figures for France, Germany, and the United Kingdom are calculated by applying annual adjustment factors to current published
data, and therefore should be viewed as less precise indicators of unemployment under U.S. concepts than the annual figures. See "Notes on the data" for information on breaks in series. For further qualifications and historical data, see Comparative Civilian Labor Force Statistics, Ten Countries, 1959-1998 (Bureau of Labor Statistics, Oct. 22, 1999).

Based on the 1992 BLS Occupational Injury and Illness Classification Structures.
2 The BLS news release issued August 12, 1998, reported a total of 6,218 fatal work injuries for calendar year 1997. Since then, an additional 20 job-related fatalities were identified, bringing the total job-related fatality count for 1997 to 6,238 .

3 Includes the category "Bodily reaction and exertion."

NOTE: Totals for major categories may include subcategories not shown separately. Percentages may not add to totals because of rounding. Dash indicates less than 0.5 percent.

The Superintendent of Documents operates 24
U.S. Government Bookstores where you can browse through shelves of information products before purchasing. Naturally, the stores can't stock all 10,000-plus titles in our inventory. But they do carry the titles you're most likely to be looking for.

[^0]:    Editor-in-Chief: Deborah P. Klein - Executive Editor: Richard M. Devens, Jr. - Managing Editor: Anna Huffman Hill - Editors: Brian I. Baker, Bonita L. Boles, Leslie Brown Joyner, Lawrence H. Leith, Mary K. Rieg • Book Reviews: Roger A. Comer, Ernestine Patterson Leary - Design and Layout: Catherine D. Bowman, Edith W. Peters - Contributors: Steven Haugen, Stanley W. Suchman

[^1]:    ${ }^{1}$ Estimates shown in this table for union and nonunion workers combined may differ slightly from estimates shown in other tables for full-time wage and salary workers because of differences in the way survey responses are weighted. Questions on union membership are asked of approximately onequarter of the CPS sample each month, whereas most other questions are asked of the full sample. Estimates in the table were tabulated using quarter-

[^2]:    Note: Dash indicates fewer than 75,000 workers.

[^3]:    Note: Sums of percentages participating in each type of health plan do not equal total because about 1 percent of full-time workers are covered by other plans, primarily exclusive-provider organizations, which are groups of hospitals and physicians that contract to provide medical services. Medium and

[^4]:    Note: Dash indicates fewer than 75,000 workers.
    Source: Current Population Survey, February 1997.

[^5]:    ${ }^{1}$ Estimates shown in this table for union and nonunion workers combined may differ slightly from estimates shown in other tables for full-time wage and salary workers because of differences in the way survey responses are weighted. Questions on union membership are asked of approximately onequarter of the CPS sample each month, whereas most other questions are asked of the full sample. Estimates in this table were tabulated using quartersample weights and therefore may differ slightly from estimates shown in other tables in this article that were tabulated using full-sample weights.

    Nоте: Dash indicates fewer than 300,000 workers.
    SOURCE: Current Population Survey, February 1997.

[^6]:    See footnotes at end of table.

[^7]:    ${ }^{1}$ Annual numbers of passengers carried starting in 1938 can be found in the "Safety Record of U.S. Airlines," Air Transport Association, on the Internet at http://www.air-transport.org.
    ${ }^{2}$ Real fares also are from the Air Transport Association, on the Internet at http://www.air-transport.org.
    ${ }^{3}$ Estimates of employment in this article are from the bls Current Employment Statistics (CES) survey of establishments, unless otherwise noted. The CES program produces estimates of employees on all nonfarm payrolls, except in private households, based on a monthly survey of about 390,000 work sites. Data from the survey appear in the Bureau's

[^8]:    The Panel Study of Income Dynamics (PSID), begun in 1968, is conducted by the Survey Research Center, Institute for Social Research, University of Michigan. The PSID is a longitudinal study of a representative sample of U.S. individuals (men, women, and children) and the family units in which they reside. It emphasizes the dynamic aspects of economic and demographic behavior, but its content is broad, including sociological and psychological measures. As a consequence of low attrition rates and the success of recontact efforts, the sample size has grown dramatically in recent years, from about 7,000 core households

[^9]:    ${ }^{1}$ Quarterly data seasonally adjusted.
    ${ }^{2}$ Annual changes are December-to-December changes. Quarterly changes are calculated using the last month of each quarter.
    ${ }^{3}$ Goods-producing industries include mining, construction, and manufacturing. Service-producing industries include all other private sector industries.

[^10]:    ${ }^{1}$ Seasonally adjusted. "Quarterly average" is percent change from a quarter ago, at an annual rate.

[^11]:    ${ }^{\mathrm{P}}=$ preliminary

[^12]:    See footnotes at end of table.

[^13]:    ${ }^{p}=$ preliminary.
    NOTE: See "Notes on the data" for a description of the most recent benchmark revision.

[^14]:    ${ }^{p}=$ preliminary.
    NOTE: See "Notes on the data" for a description of the most recent benchmark revision. Dash indicates data not available.

[^15]:    Cost (cents per hour worked) measured in the Employment Cost Index consists of wages, salaries, and employer cost of employee benefits.
    ${ }^{2}$ Consists of private industry workers (excluding farm and household workers) and State and local government (excluding Federal Government) workers.
    ${ }^{3}$ Consists of legislative, judicial, administrative, and regulatory activities.
    ${ }^{4}$ This series has the same industry and occupational coverage as the Hourly Earnings index, which was discontinued in January 1989.
    ${ }^{5}$ Includes, for example, library, social, and health services.

[^16]:    See footnotes at end of table

[^17]:    ${ }^{1}$ Consists of private industry workers (excluding farm and household workers) and ${ }^{3}$ This series has the same industry and occupational coverage as the Hourly State and local government (excluding Federal Government) workers. Earnings index, which was discontinued in January 1989.
    ${ }^{2}$ Consists of legislative, judicial, administrative, and regulatory activities
    ${ }^{4}$ Includes, for example, library, social, and health services.

[^18]:    Agricultural and government employees are included in the total employed and total working time; private household, forestry, and fishery employees are excluded. An explanation of the measurement of idleness as a percentage of the total time worked is found in "'Total economy' measures of strike idleness," Monthly Labor Review, October 1968, pp. 54-56.
    ${ }^{\mathrm{p}}=$ preliminary.

[^25]:    See footnotes at end of table

[^26]:    ' Quarterly rates are for the first month of the quarter.

    - Data not available.

[^27]:    Data for 1994 are not directly comparable with data for 1993 and earlier years. For ${ }^{3}$ Labor force as a percent of the working-age population. additional information, see the box note under "Employment and Unemployment Data" in the notes to this section.
    ${ }^{2}$ Data from 1991 onward refer to unified Germany. See Comparative Civilian Labor NOTE: See "Notes on the data" for information on breaks in series for the United Force Statistics, Ten Countries, 1959-1998, October 22, 1999, on the Internet at States, France, Germany, Italy, the Netherlands, and Sweden http://stats.bls.gov/fisdata.htm.

[^28]:    - Data not available.

[^29]:    1 Data for 1989 and subsequent years are based on the Standard Industrial Classification Manual, 1987 Edition. For this reason, they are not strictly comparable with data for the years 1985-88, which were based on the Standard Industrial Classification Manual, 1972 Edition, 1977 Supplement.
    ${ }^{2}$ Beginning with the 1992 survey, the annual survey measures only nonfatal injuries and illnesses, while past surveys covered both fatal and nonfatal incidents. To better address fatalities, a basic element of workplace safety, BLS implemented the Census of Fatal Occupational Injuries.
    ${ }^{3}$ The incidence rates represent the number of injuries and ilinesses or lost workdays per 100 full-time workers and were calculated as (N/EH) X 200,000, where:
