Bureau of Labor Statistics

Employment Outlook, 2002-12

Concepts and context • U.S. economy • Labor force • Industry output and employment • Occupational employment

U.S. Department of Labor Elaine L. Chao, Secretary

Bureau of Labor Statistics Kathleen P. Utgoff, Commissioner

The Monthly Labor Review (usps 987–800) is published monthly by the Bureau of Labor Statistics of the U.S. Department of Labor. The Review welcomes articles on the labor force, labor-management relations, business conditions, industry productivity, compensation, occupational safety and health, demographic trends, and other economic developments. Papers should be factual and analytical, not polemical in tone. Potential articles, as well as communications on editorial matters, should be submitted to:

Editor-in-Chief

Monthly Labor Review

The February Review

The BLS Occupational Outlook Handbook is far and away the most popular sub-section of the BLS Web site. The Handbook home page received more than 500,000 page views in December 2003, and the index of professional occupations was viewed almost 100,000 times. The projections that the articles in this issue present are the quantitative underpinnings of the Handbook and its evaluation of prospects in specific occupations. Thus, we think, it was worth the wait while the projections staff made their transition to the new North American Industry Classification System (NAICS).

Michael W. Horrigan, the Assistant Commissioner in charge of the employment projections program, provides an overview of the concepts and methods used to make the individual projections and the interactions among them. He also summarizes the results of each stage of the process.

Betty W. Su establishes the macroeconomic framework the rest of the projections will assume prevails in 2012: A \$12.6 trillion dollar economy (in chained 1996 dollars) with a projected growth rate of GDP of about 3.0 percent and a projected productivity growth rate of 2.1 percent.

Mitra Toossi uses long-term population projections provided by the Census Bureau and an analysis of historical trends in labor force participation to project the labor supply scene in 2012: An overall labor force that has grown from 144.9 million in 2002 to 162.3 million in 2012—a growth rate of about 1.1 percent per annum.

Jay M. Berman reports on the detailed industry by industry flow of inputs and outputs. As mentioned above, the fact that this uses the new NAICS represents a significant break from the past use of the old-shoe Standard Industrial Classification (SIC) system.

On the basis of the industry production and employment needs reported above, combined with industry-occupation staffing patterns developed by the Occupational Employment Survey, Dan Hecker presents projected trends in occupational employment in 2012.

Union membership 2003

In 2003, 12.9 percent of wage and salary workers were union members, down from 13.3 percent in 2002. The union membership rate has steadily declined from a high of 20.1 percent in 1983, the first year for which comparable union data are available.

Union membership rates were higher for men (14.3 percent) than for women (11.4 percent) in 2003. The gap between men's and women's rates has narrowed considerably since 1983, when the rate for men was 10 percentage points higher than the rate for women. Blacks were more likely in 2003 to be union members (16.5 percent) than were whites (12.5 percent), Asians (11.4 percent), or Hispanics (10.7 percent).

Among occupational groups, education, training, and library occupations (37.7 percent) and protective service workers (36.1 percent) had the highest unionization rates in 2003. Natural resources, construction, and maintenance workers and production, transportation, and material moving occupations also had higher-than-average union membership rates at 19.2 percent and 18.7 percent, respectively. Among the major occupational groups, sales and office occupations had the lowest unionization rate—8.2 percent. Find out more in "Union Members in 2003," news release USDL 04-53.

Real weekly earnings flat in 2003

Average weekly earnings rose by 1.7 percent, seasonally adjusted, from December 2002 to December 2003. After deflation by the CPI-W, however, average weekly earnings were unchanged.

Before adjustment for seasonal change and inflation, average weekly earnings were \$523.02 in December 2003, compared with \$520.37 a year earlier. After adjustment for seasonality, weekly earnings were \$522.35 in December 2003 and \$513.76 in December 2002. Expressed in constant 1982 dollars, seasonally-adjusted weekly earnings were \$280.44 and \$280.53 in the final months of 2002 and 2003, respectively. For more information see, "Real Earnings in December 2003," news release USDL 04-30.

Productivity in retailing

In 2002, labor productivity—as measured by output per hour—rose in four of the six largest retail trade industries (those with more than one million employees). Productivity grew 4.2 percent in the entire retail trade sector in 2002. Output increased by 3.3 percent while hours fell by 0.9 percent.

Among the largest retail industries, productivity increased 3.1 percent in grocery stores, 3.9 percent in building material and supplies dealers, 6.2 percent in clothing stores, and 10.9 percent in other general merchandise stores (such as warehouse clubs, catalog showrooms, and dollar stores). Labor productivity declined 1.0 percent for department stores and 2.6 percent for automobile dealers. Additional information is available from "Productivity and Costs: Wholesale Trade, Retail Trade, and Food Services and Drinking Places, 2002," news release USDL 03-972.

Employment outlook, 2002-12

Employment projections to 2012: concepts and context

BLS projections are carried out against a background of explicit assumptions and model-based findings that connect the past to the future; the projections form the basis for providing information on entering the job market, changing careers, and choosing appropriate educational and training paths to job success

Michael W. Horrigan

presents the BLS employment outlook for the period from 2002 to 2012. The 2012 projections continue a longstanding tradition of BLS examinations of future job prospects dating back more than 50 years. First begun to assist returning World War II veterans back into the world of work, the BLS projections program has grown steadily from a project that reported simple descriptive material about available occupations to an undertaking encompassing a model-based approach that develops projections of the macroeconomy, the labor force, industry employment and output, and occupational employment growth.

The BLS projections are based on a long-term view of the U.S. economy that assumes a long-run full-employment economy in which labor markets clear. As a result, BLS projections address the question, "How would employment in industries and occupations grow if the economy were to operate at its full potential a decade from now?" In the article "The U.S. economy to 2012: signs of growth," which focuses on projected trends in the macroeconomy, Betty W. Su reports the results of a macroeconomic model according to which the overall U.S. economy is expected to grow from \$9.4 trillion in 2002 to \$12.6 trillion in 2012 (measured in

chain-weighted 1996 dollars). This increase represents a growth rate of 3.0 percent per year in the real gross domestic product (GDP) of the economy. On the basis of the results from the macroeconomic model, the unemployment rate in 2012 is projected to be 5.2 percent and the annual rate of growth of productivity is expected to be 2.1 percent. Given these broad indicators of economic growth, the model used to describe macroeconomic activity provides detailed projections of four categories of expenditures: personal consumption, investment, government, and foreign trade. These projections are necessary as input to the industry projections that, in turn, form the basis of the occupational projections.

Another major factor to consider in projecting the path of the U.S. economy is the available labor supply over the next decade. In the article "Labor force projections to 2012: the graying of the U.S. workforce," Mitra Toossi uses Census Bureau population projections based on the 2000 census, along with historical trends in labor participation rates, to project labor force levels and participation rates for 136 age, sex, and race or ethnicity groups over the 2002–12 period. Overall, the Bureau of Labor Statistics expects the labor force to grow from 144.9 million in 2002 to 162.3 million in 2012, an annual growth rate of approximately 1.1 percent.

Michael W. Horrigan is Assistant Commissioner, Office of Occupational Statistics and Employment Projections, Bureau of Labor Statistics. E-mall: Horrigan_Michael@bls.gov

The third major area of analysis translates the growth in the macroeconomy into the levels of final market output of each industry and the levels of intermediate inputs that are purchased by each industry to produce that output. In the article "Industry output and employment projections to 2012," Jay M. Berman reports that the flow of goods and services purchased in the production process or delivered to the market as final products will reach a total of \$23.2 trillion in chain-weighted 1996 dollars) in 2012. The number of jobs needed to support this level of economic activity is expected to grow from 144.0 million to 165.3 million. The 2002-12 projections present detailed industry flows of inputs and outputs, using the 2002 North American Industrial Classification System (NAICS). This is the first set of BLS employment projections developed from the NAICS; past projections utilized the 1987 Standard Industrial Classification System (SIC). The 2004–2005 BLS Career Guide to Industries, a companion publication to the BLS projections, offers a detailed description of NAICS-based industries and the impact the changeover will have on industry and occupational employment over the 2002-12 period.

On the basis of the description of industry production and total employment needs reported in the three articles, data from the Occupational Employment Survey (OES) are used to project the occupational staffing patterns needed in each industry. The OES gives detailed occupational employment information on each of the NAICS-based industries. These data are coupled with expert assessment of likely trends to produce employment projections for 725 detailed occupations. In the article "Occupational employment projections to 2012," Dan Hecker reports the results of the BLS analysis of the projected trends in the occupational employment that produces the goods and services of the U.S. economy. The occupational information provided in this article includes estimates of selfemployment that are based on data from the Current Population Survey (CPS). Total employment is projected to increase by 14.8 percent, reflecting a net employment growth of 21.3 million jobs over the 2002-12 period. The number of job openings due to both net employment growth and net replacement needs is projected to be 56.3 million. Self-employment is projected to decline 2.3 percent, from 11.5 million to 11.2 million. A separate companion publication, the 2004-2005 BLS Occupational Outlook Handbook, gives a detailed description of more than 300 occupations; the book is widely used by students and jobseekers to obtain career advice.

Together, the four articles presented in this issue of the *Review* offer a wealth of detail on projected trends in the macroeconomy, the labor force, industry output and employment, and occupational employment growth. The purpose of this overview is to present some of the most significant findings that emerge from the articles and to provide an overall context from which to view them. Accordingly, the sections that follow examine the potential

impact of baby-boomer retirements, occupational labor shortages, immigration, and high-paying, fast-growing occupations on the economy over the 2002–12 period.

Any attempt to project the direction and path of the U.S. economy and, in particular, longer run occupational employment needs, is subject to a great deal of uncertainty. The BLS approach is to state the underlying assumptions clearly and present the model-based findings about the long-run position of the economy in as transparent and objective a manner as possible. The Bureau has an ongoing tradition of evaluating its estimates against the actual state of the economy in the end year of the projections. Waiting 10 years to judge the accuracy of the projections, however, belies the more pressing need to assess the reasonableness of the BLS description of the likely secular long-run trends in the economy and their implications for occupational employment trends. The next section examines this subject.

A comparison of macroeconomic trends

One standard for assessing the reasonableness of the BLS description of the long-run position of the U.S. economy is to compare how the description of the next 10 years stands with respect to the past behavior of the economy on the basis of a broad set of macroeconomic indicators. Toward that end, the following tabulation, based on data from the Bureau of Economic Analysis, compares peak quarters, about 10 years apart, of U.S. business cycles in the post-World War II era (the last period listed, 2000–12, based on annual data, represents a comparison between the last full year of the 1991–2001 expansion with the ending year of the BLS projections—which, as noted earlier, represents a level of economic activity associated with the economy operating at its full potential):

| Years spanned | Annual average growth rate of real GDP (percent) |
|---------------------------------------|---|
| 1960, quarter II, to 1969, quarter IV | 4.4 |
| 1969, quarter IV, to 1980, quarter I | 3.3 |
| 1980, quarter I, to 1990, quarter III | 2.9 |
| 1990, quarter III, to 2001, quarter I | 3.1 |
| 2000 through 2012 | 2.7 |

The expansion of the U.S. economy has slowed considerably since the 1960s, from an annual rate of 4.4 percent between 1960 and 1969 to around 3 percent per year since 1980. Based on the BLS projection of GDP for 2012, the projected growth rate of 2.7 percent over the 2000–12 period is in line with the rate exhibited during the last two decades. (This growth rate, which covers the 2000–12 period, including the 2001 recession, is slightly lower than the 3.0-percent growth rate posted over the 2002–12 projection period; the box on the next page compares the 2000–10 and 2002–12 BLS projections.)

Comparing the 2000-10 and 2002-12 projections

Since the publication of the Bureau's most recent set of projections, covering the 2000–10 period, the U.S. economy entered a recession in March 2001 and has been in recovery since December of the same year. One of the hallmark features of the recovery period from December 2001 to August 2003 was the continued net employment losses after the official end of the recession. The term job-loss recovery has been used to describe that aspect of the economy whereby significant output gains and strong labor productivity occurred together with continued contraction in employment. The juxtaposition of the BLS long-run projections, which assume an economy operating at capacity, with this most recent experience in job losses is striking enough to ask, "To what extent are the current projections influenced by the events of the last recession and the current recovery?"

While the model presented in the text projects a secular trend instead of pinpointing cyclical downturns or upturns, the trend is certainly affected to a degree by the current position of the economy. The long-run-growth trajectory of an economy that is in its ninth year of recovery or expansion, as the 2000-10 projections assume, may certainly look different from the long-run-growth trajectory associated with an economy in its first year of recovery, as the 2002–12 projections presuppose. But how much different? The growth rate projected for GDP for the 2000-10 period was 3.4 percent per year, compared with the 3.0 percent projected for the 2002-12 period. The model presented in the text implies a 5.2-percent long-run unemployment rate in the current projections, higher than the 4.0 percent postulated in the previous set of projections. Labor productivity is also somewhat lower, at 2.1 percent for the 2002-12 projections, compared with the 2.4percent annual growth rate assumed in the 2000-10 projections. Although a more detailed comparison will reveal other differences, in general, the long-run growth trajectory in the current set of projections is not quite as strong as in the previous set, reflecting, to a certain extent, the impact of the last recession.

Productivity trends since 1995. One of the most fascinating and significant features of the current U.S. economy is the strength of both labor and multifactor productivity since 1995. Chart 1 shows the annual rate of growth of labor productivity between selected peak quarters of the U.S. economy. Included for comparison are the periods from 1990, quarter III, to 1995, quarter I, and from 1995, quarter I, to 2001, quarter I, the latter period being one of exceptional strength in productivity that has continued to this day. Between quarter III of 1990 and quarter I of 1995, labor productivity grew at an annual average rate of 1.5 percent, compared with an annual average growth rate of 2.3 percent between quarter I of 1995 and quarter I of 2001. Over the 2002–12 period, the Bureau projects an annual average growth rate of output per hour of 2.1 percent, just slightly lower than the rate of the 1995–2001 period.

Perhaps even more telling was the strength of labor productivity during the most recent recession. Chart 2 shows the annual average rate of labor productivity during each of the recessions since 1960. The strength of productivity that began in 1995 continued unabated during the most recent recession, setting the stage for continued strong growth in productivity over the 2002–12 period.

Industry trends

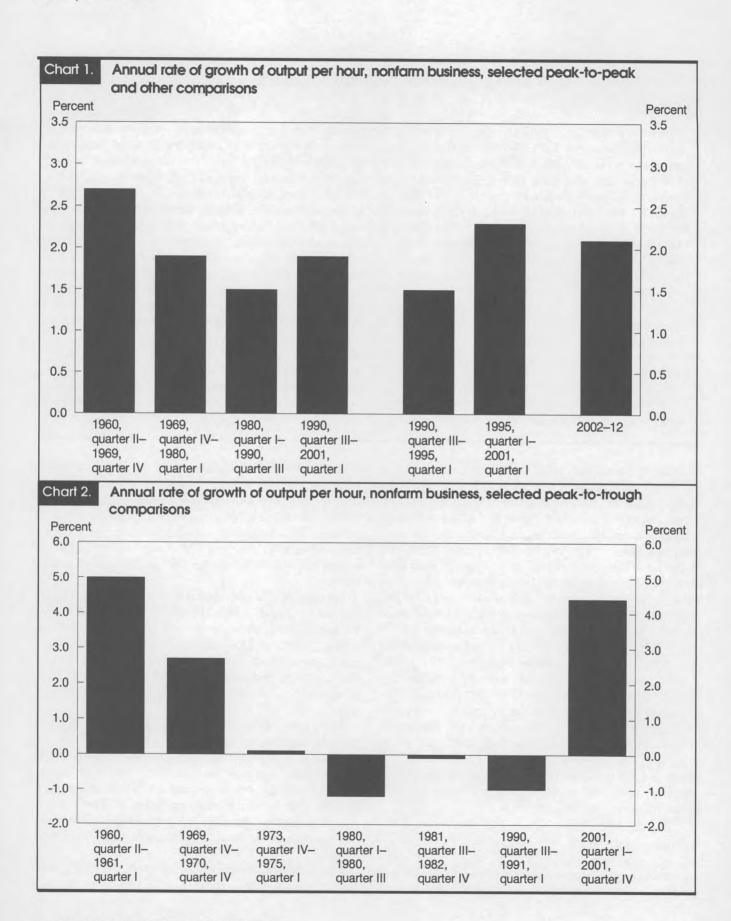

Output and employment by industry. Trends in overall labor productivity, while important, still tell only one part of the

story. How these trends are reflected in the growth in output by industry and, in particular, between goods-producing and service-providing industries, affords an important insight into the sources of overall employment growth in the BLs projections. Table 1 compares goods-producing and service-providing sectors for the year 2002, based on the proportions of total output and total employment accounted for by each sector.

The measure of output reported in the table is nominal gross duplicated output, which includes output produced for intermediate sale to other firms and final output delivered to markets.² Nominal gross duplicated output has the closest connection to the amount of labor that industries will need to hire to achieve production goals, whether such output is for intermediate sale to another firm or for sale as a final market good.

As the table indicates, the goods-producing sector's share of gross duplicated output is substantially higher than its share of total nonfarm wage and salary employment, especially for manufacturing industries. In contrast, the service-providing sector's share of gross duplicated output, 67.1 percent, is smaller than its 82.0-percent share of employment. Two notable exceptions are the information and financial activities sectors, which both account for a larger share of output than employment.³

Given these differences between goods-producing and service-providing industries, it is not surprising that the

Bureau projects that net change in nonfarm wage and salary employment over the 2002–12 period will be largely in the service-providing industries: 20.8 million (96.3 percent) out of a projected net employment gain of 21.6 million. Nor should it be surprising that goods-producing industries account for 22.8 percent of the projected increase in output, measured on a nominal gross duplicated basis, and only 3.7 percent of the net employment change over the same period. (See table 2.)

Do these figures mean that there will be very few job opportunities in goods-producing industries? Not at all. The reason is that the BLS projections are based on net employment change and do not reflect the underlying dynamic flows of hirings and separations that occur within industries. How much turnover is there by industry? The Bureau now calculates job turnover statistics by industry in its new Job Opening and Labor Turnover Survey (JOLTS). Table 3 shows the breakdown of turnover by major NAICS industry group in September 2003, the latest month for which data were available at the time this article was written. In the private sector, 4.2 million individuals were hired during September 2003, representing 3.8 percent of private nonfarm payroll employment that month. Also, 4 million workers were separated from their jobs during September, accounting for 3.7 percent of employment. An examination of the industries listed in table 3 shows how dynamic U.S. labor markets are across industries.

Another measure of the dynamic nature of labor markets is the number of job openings that are created to replace workers who leave occupations. Hecker lists the number of job open-

2 Industry output levels do not add to totals, due to the exclusion of

ings for each detailed occupation over the 2002–12 period, a figure that represents the hiring required both to meet net employment growth and to replace workers who leave each occupation.⁴ As noted previously, the Bureau projects an overall level of job openings of 56.3 million jobs over the period, representing a net employment growth of 21.3 million and an additional 35 million job openings due to replacement needs.

While a principal and highly popular use of BLS projections is to offer guidance on which occupations are projected to grow the fastest or add the most jobs, the projected trends are closely tied to the underlying changes in industry output and employment levels. An industry that is projected to have a significant increase in the level or the rate of growth of its output can have a significant impact on the types of occupations that will be in demand over the next decade. One reason for this relationship has to do with the concentrations of particular occupations in specific industries. For example, 49 percent of registered nurses work in hospitals, and another 17 percent work in offices of physicians and in ambulatory health-care centers, including home health-care centers. The projected increases of 27 percent and 57 percent in the real output of hospitals and ambulatory health-care services, respectively, translates into 71 percent of the nearly 623,000 total projected increase in the employment of registered nurses.

Another important influence of industries on the occupational staffing mix results from changes in the technology of production—which can have significant impacts on the types of

| | | evels | Shares | | |

¹ Gross duplicated output, measured in nominal dollars.

agriculture, forestry, fishing, and hunting industries, as well as special industries and a residual category.

workers employed as new production technologies are adopted. In 1983, for example, the production of computer and office equipment required the services of nearly 100,000 precision production, craft, and repair workers and 7,000 computer engineers, scientists, and systems analysts. By 1998, as innovations in the production of computer and office equipment were introduced into this industry, the number of production workers had dropped to 68,000, and employment in computer-related occupations had grown to more than 51,000.

A number of other factors related to industry output and employment can have an important influence on the occupational staffing patterns observed in the U.S. economy: the discovery of new technologies and their integration into the production process; the influence of global competition; the different emphases placed by industries on research and development, marketing, and output customization; and the outsourcing of functions to firms in other domestic industries or abroad, among others.

Fast employment growth, high output growth

With the aforementioned multiple factors affecting industry output, are there ways of summarizing the likely impact of industry trends on occupational employment? One approach is to group industries on the basis of selected characteristics and examine the employment growth (or decline) that is projected for those industries over the next decade. Berman lists (1) the industries that are projected to have the fastest-growing and

most rapidly decining employment growth,⁵ (2) the industries with the fastest-growing and most rapidly decining output growth,⁶ (3) the industries with the largest employment growth and declines,⁷ and (4) the industries with the largest output growth and declines.⁸ Another grouping that provides insight into employment and occupational staffing patterns is the set of industries that are projected to post relatively high rates of growth in *both* output and employment. Table 4 lists industries that are projected to have employment increases greater than 14.8 percent (the overall increase in employment projected for the 2002–12 period). The industries are listed in descending order of their projected output growth over the 2002–12 period.

The first row of the table shows that the Internet services, data processing, and other information services industry is projected to have the highest annual rate of change of real output over the projection period: 10.3 percent per year. This industry is expected to add 244,000 jobs, an increase of 46.2 percent, over the period. Twenty-one industries are projected to have real output growth rates that equal or exceed the overall annual average of 4.0 percent. The last two columns indicate that these industries together accounted for 14 percent of nonfarm wage and salary employment in 2002 and are projected to account for 32 percent of overall net employment growth over the projection period.

If the list of industries with fast employment growth is extended to include those with average annual output growth of 3 percent or more per year, 35 industries qualify. These industries

² Industry output levels do not add to totals, due to the exclusion of

account for 24 percent of nonfarm wage and salary employment in 2002 and 48 percent of their net employment growth over the 2002–12 period. Note that not all 35 industries are in the service-providing sector of the economy. Although goods-producing industries generally have greater output than employment gains, the list of 35 industries includes metalworking machinery manufacturing industries; forging and stamping industries; plastics product manufacturing industries; and architectural and structural metals manufacturing industries.

The 50 industries with average annual output growth of 2 percent or more per year and employment growth exceeding 14.8 percent account for 65 percent of nonfarm wage and salary growth over the projection period. Further, a total of 84 percent of employment growth is accounted for by all of the industries with projected net employment growth exceeding the overall average of 14.8 percent. This total of 58 industries accounted for 55 percent of employment in 2002, and each has a projected annual average growth rate of real output of at least 1 percent between 2002 and 2012.

Trends in labor supply

One of the most significant influences on both labor force growth and labor force participation rates in the last 50 years has been the aging of the baby-boom cohort. Indeed, one of the recurring

Source: Job Openings and Labor Turnover Survey, Bureau of Labor Statistics.

themes that run through the four articles in this issue of the *Review* is the influence of the baby-boom generation on everything from consumer expenditures to housing, medical care, and retirement, to name just a few factors.

The baby boomers were born between 1946 and 1964, were aged 38 through 56 in 2002, and will be aged 48 through 66 in 2012. In table 5, boldface is used to denote when the baby boomers reached (or will reach) various age groups between 1950 and 2010. One way to see the impact of this cohort is to compare the size of an age group before the arrival of the baby boomers with its size once the baby boomers have reached the indicated ages. For example, in 1970, the baby boomers were aged 6 to 24 years, and in that year, there were 48 million individuals aged 25 to 44. Twenty years later, with the baby boomers aged 26 to 44, the number of individuals in the 25–44 age group stood at 80.8 million, an increase of 68.3 percent.

Perhaps the aspect of the baby boomers that is generating the most interest at present is their potential impact on the remaining size of the labor supply as the boomers enter older age groups and begin to retire. According to Census Bureau population projections given in the table, by 2010, when baby boomers will be 46 to 64 years, the number of 55- to 64-year-olds will grow by more than 11 million compared with the number in 2000, an increase of 46 percent.

One question that naturally arises is whether the baby boomers have had a discernible impact on labor force participation rates. That is to say, as the baby boomers have aged, have their labor force participation rates differed significantly from the cohorts that came before them or the cohorts that followed them? Table 6 provides the answer. For men, the dominant feature is the declining participation rates among those aged 55 and older since 1950, a group that does not yet include the baby boomers. From an examination of the younger age groups listed in the table, it does not appear that the labor force participation rates of baby boomers differed significantly from those of similarly aged cohorts that came before or after.

The table also shows the remarkable rise in the labor force participation rates for women since 1950, especially among the prime working-age groups from 25 to 54 years. In each case, the rising trend predates the arrival of female baby boomers. Although these women certainly contributed to the trend, the data do not support the idea that the rising labor force participation rates of women since 1950 were the result of the entry of the baby-boomer cohorts.

In Toossi's article on labor force projections, changes in the labor force levels of various age groups are decomposed into changes in the size of the population and changes in the labor force participation rates of each age group. Consistent with the findings just given, Toossi finds that changes in labor force levels of each age group are largely the result of changes in the size of the population in various age groups, rather than changes in their underlying labor force participation rates.

Labor shortages

There is a growing interest in the potential impact of the upcoming retirement of baby boomers-specifically, the prospect of a general shortage of workers and its effects on specific occupational labor markets. Table 7 gives the actual and expected sizes of the labor force by age group between 1950 and 2050, by decade, based on previously published research by Toossi.9 The arrival on the economic scene and the subsequent aging of the baby boomers has had a significant impact on labor force growth rates. Between 1950 and 2000, the civilian labor force grew by 79 million, from 62.2 million to 140.9 million, an increase of 1.6 percent per year. The Bureau projects that, between 2000 and 2010, labor force growth will slow to 1.1 percent per year, and after the retirement of the baby boomers, between 2010 and 2020, labor force growth will slow to 0.4 percent per year. Overall, the civilian labor force is expected to grow by 51 million between 2000 and 2050, a slowdown to a 0.6-percent increase per year.

Will these increases in the size of the labor force be too small to meet the needs of the U.S. economy? Will there be a general shortage of workers, so that many of the jobs needed to produce

the level of output demanded by the economy (and by U.S. trading partners in the form of exports) will go unfilled? To what extent do the projections account for this possibility? Consider the latter question first. The BLs projections, as mentioned earlier, assume a labor market that clears. The Bureau does not base its estimates of changes in total, industry, or occupational employment on labor markets that have either a shortage or a surplus of workers. Despite this assumption, numerous analyses have been produced by researchers in past years using BLs employment projections as a basis for measuring what is believed to be evidence of a future shortage of workers in the U.S. economy.

One of the most common ways in which BLS numbers are used to project a "coming shortage" is by asserting that the difference between the projected labor force level and the projected employment count represents a shortage of workers. For example, the Bureau projects a labor force of 162.3 million individuals in 2012. At the same time, the Bureau expects that the 2012 economy will require that 165.3 million jobs be filled. Does this difference imply a shortage of 3.0 million workers come 2012? Absolutely not-but if not, then what accounts for the difference? First, BLS projections of occupational employment are based on the number of jobs that the economy is expected to require. However, because individuals can and do hold more than one job, the count of workers will most certainly be less than the number of jobs. Second, and more technically, the data the Bureau uses for projecting industry employment are based on the Current Employment Statistics survey, which counts payroll jobs at establishments. The data the Bureau uses to project labor force levels, by contrast, are based on the CPS, a household survey yielding estimates of the number of individuals in the labor force. Besides multiple jobholding, then, there are statistical differences between these two series that contribute to the difference between the job count and the count of individual employees in BLS projections.

Essentially, the BLS projections are based on an examination of the labor required to produce projected levels of output by industry. How industries manage their human resource requirements is influenced by a great many factors: the available labor supply (including immigration), the skill levels of prospective jobseekers, the use of technology in the production process, the required capital-labor ratio consistent with the technology used for production, how work is organized, the use of employees from the personnel supply services industry, the hiring of self-employed contractors, the use of flextime and flexiplace, the use of overtime or mandatory shift coverage, and the hiring of offshore labor in foreign countries, among others. Although the projections do not attempt to explicitly model these various possible management options that firms may exercise, a perspective on their potential importance is certainly necessary to consider in building any set of projections and, in particular, detailed descriptions of the outlook for occupations. The next two subsections examine two areas of growing interest in assessing the reaction of firms to the available qualified labor

¹ Fast employment growth is defined as a projected percentage in employment greater than 14.8 percent, the overall average for the 2002–

supply: immigration and the outsourcing of the production of goods and services to establishments based in foreign countries.

The potential role of immigration in increasing the available supply of labor. Rising trends in immigration levels to the United States, especially over the last decade, are one source of labor for occupations in which it may be increasingly difficult to find qualified workers. The following tabulation shows the levels and rates of immigration to the Nation, by decade, since 1901, as compiled by the U.S. Census Bureau:

| Period | Number of immigrants entering United States | Rate per thousand U.S. population |
|---------|---|-----------------------------------|
| 1901-10 | 8,795,000 | 10.4 |
| 1911-20 | 5,736,000 | 5.7 |
| 1921-30 | 4,107,000 | 3.5 |
| 1931-40 | 528,000 | .4 |
| 1941-50 | 1,035,000 | .7 |
| 1951-60 | 2,515,000 | 1.5 |
| 1961-70 | 3,322,000 | 1.7 |
| 1971-80 | 4,493,000 | 2.1 |
| 1981–90 | 7,338,000 | 3.1 |
| 1991–98 | 7,605,000 | 3.6 |

The population projections from the Census Bureau that are used as the basis for BLS labor force projections include an estimate of the level of legal immigration to the United States over the next decade. In its most recent population projections, the Census Bureau estimates annual immigration levels of 1.1 million from 2000 to 2005, a decline to 900,000 per year from 2006 to 2010, and an increase to 1.3 million annually from 2011 to 2012.

Much uncertainty accompanies any discussion of the role of immigration in addressing pressures on labor markets to find qualified workers. Changes in immigration policy, the occupational and educational profiles of new immigrants, and the regional impacts of where immigrants choose to live are but a few of the somewhat speculative areas that make assessing this potential problematic. To the extent that past serves as prologue, however, the preceding tabulation does suggest that there will be substantial levels of immigration into the United States over the next decade.

What kinds of occupations do recent immigrants enter? Using data from the CPS for the period 2000–02, table 8 lists occupational employment distributions for immigrant groups based on the number of years since their immigration into the Nation, compared

¹² projection period.

with the distribution for all U.S. employees. Individuals who have immigrated within the last 5 years have a greater likelihood than the overall population of U.S. workers of being in food preparation and serving related occupations, production occupations, and construction trades. They also have a greater likelihood of being in computer and mathematical occupations. As the number of years since immigration increases, the occupational distribution of immigrants begins to broadly resemble the overall occupational distribution, although immigrants still have a greater likelihood of being in production and food-related occupations, compared with all U.S. employees.

The potential role of hiring offshore employees. One of the areas of increasing interest in U.S. labor markets is the use of offshore employees as part of the production process for U.S. firms. Outsourcing work to foreign countries—that is, purchasing services formerly produced in the United States from establishments in other countries—has been widely cited in recent months as having a growing impact on U.S. employment. The exact magnitude of outsourcing is not known, owing to the lack of specific, systematic data on the use of foreign employment to produce outsourced goods and services. Outsourcing is a trend that has been going on for quite some time. The current interest in it appears to reflect a transition from the importation of goods to the

direct purchase of foreign-produced services, a phenomenon that has expanded with the development of the Internet and its dissolution of temporal and spatial barriers to the free flow of services.

What is the potential impact of this transition? Domestic industries have already outsourced such functions as accounting, marketing, and advertising to other domestic industries that both specialize in these services and produce them more cheaply. With outsourcing, a purchase of a service from another industry replaces all the material and labor inputs that the purchasing industry previously used internally in order to create that service. The total output of the industry now buying the service from an outside source is somewhat lower, reflecting the inherent costefficiency of the industry producing the service. Some of the purchasing industry's employment is shifted to the producing industry, while some is freed up for other jobs in the economy. The productivity of the remaining employees in the purchasing industry now appears to be somewhat higher. If the outsourcing is provided by a foreign establishment, the output of the purchasing industry is again little affected. The jobs outsourced, however, are no longer counted in U.S. employment totals, and because imports are removed in total from the GDP accounts, GDP is lower.

Foreign outsourcing influences the projections through its impact on the industry distribution of GDP. As industries import more foreign services, the trend toward higher importation will be reflected in the relative declines in the output and employment of the affected industries over time. Because the Bureau bases its industry employment projections largely on trend analyses of detailed establishment-based time series, the effects of the recent past have been implicitly addressed to the extent that the data used have already begun to reflect the situation. More explicitly, expert review of the model-based projections by BLS occu-

pational employment analysts brings to bear subjective, but current, knowledge of industry employment practices. Studies of past outsourcing trends and careful detailing of expectations for continued outsourcing in the future will ensure that foreign outsourcing is carefully accounted for in future projections prepared by the Bureau.

Labor shortages by occupation. The fact that BLS projections are based on the assumption of a labor market in balance does not mean that employers will not experience significant difficulties in finding and hiring workers in labor markets for individual occupations. One bellwether indicator of the relative difficulties that arise in hiring sufficient supplies of workers in any occupation is whether any trends show a consistent pattern of rising wages and rising employment, suggesting that the demand for workers in the occupation in question is increasing faster than the supply. Such a situation may represent a shortage, which is theoretically consistent with the persistent existence of vacancies despite rising wage offers to fill the vacant jobs. 11 Alternatively, the situation may be consistent simply with a market that is maintaining equilibrium by paying higher wages. In either case, depending on the degree of mismatch between demand and supply, especially by geographic area, there may be significant difficulties in finding workers in particular occupations.

Consider, for example, the employment and wage trends for registered nurses, an occupation often cited as having a shortage of workers. Between 1994 and 2000, a period of significant economic expansion, the net employment of usual full-time registered nurses increased by 8.9 percent, and their real wages declined by 0.2 percent, compared with an increase in real weekly wages of 6.3 percent for U.S. workers as a whole. In contrast, since 2000, despite the recession, there has been strong growth in both employment (12.5 percent) and real wages (5.9 percent) of registered nurses, suggestive of increased recent difficulties in finding adequate supplies of workers in that occupational group.

What other evidence can be gathered to develop a profile of how relatively easy or difficult it has been in recent years to find and hire registered nurses or, for that matter, workers in any other occupation—and how might that evidence be used to track similar difficulties in the future? One potentially important indicator is to calculate the percentage of an occupation that is in the 55-years-and-older age range—and, therefore, is theoretically ready to retire over the next decade. On the basis of 2002 annual averages, 13.4 percent of registered nurses in this country are aged 55 and older. The national average across all occupations is 13.9 percent.

Table 9 shows the occupations that have at least 20 percent of their employees aged 55 and older and that are projected to have net employment increases larger than the overall national average of 14.8 percent. For these occupations, the table suggests that hiring, if only for replacement purposes, is going to be fairly brisk—and the need to expand total employment levels will only serve to accentuate the hiring challenge.

| Occupation | All employees | Did not immigrate | Immigrated 1–5 years ago | Immigrated 5–10 years ago | Immigrated more than 10 years ago |
|---|---------------|----------------------|-----------------------------|------------------------------|---|

| Fransportation and material moving occupations | 6.2 | 6.1 | 7.2 | 7.3 | 6.4 |

Are there other pieces of evidence? The general problem with addressing the question whether the U.S. labor market will have a shortage of workers in specific occupations over the next 10 years is the difficulty of projecting, for each detailed occupation, the dynamic labor market responses to shortage conditions. Employers adapt to difficult hiring markets in a variety of ways: modifying the duties of a job, changing the capital-labor ratio, imposing mandatory shift coverage, and hiring contract employees, immigrants, or offshore labor in foreign countries, among other approaches. Perhaps the best that can be done is to examine as many of these indicators as possible and develop a profile of how the labor market is responding to the changes in each occupation's relative demand for, and supply of, workers.

High-paying, fast-growing occupations

While it is certainly a challenge to project future labor market shortages, another question of abiding interest is what guidance the BLS projections provide with regard to what many refer to as "hot jobs" in the U.S. economy? In his article on occupational employment, Hecker discusses the *fastest-growing* and *largest-growing* occupations. ¹² Table 10 on pages 17–21 of the current article lists occupations that are expected to grow faster than the overall average and that are known to be relatively high paying in the current economy. Table 10 also shows both the cumulative percentage of 2002 employment and the cumulative percentage of projected employment growth between 2002 and 2012 that is accounted for by these fast-growing, high-paying occupations.

The table uses the 2002 Occupational Employment Survey to identify "high-paying" occupations, defining them as any occupation whose mean annual earnings are in the top half of the overall distribution of earnings. Concomitantly, "fast-growing" occupations are defined as occupations that are projected to grow faster than 14.8 percent (again, the national average for all occupations).

A number of interesting aspects of the occupations listed in table 10 readily present themselves. For one, the list is not the exclusive domain of the fast-growing health- or computer-related occupations—although there are obviously a great many such occupations on the list. For example, a number of management-, education-, sales-, art-, architecture-, design-, and accountingrelated occupations are listed. Nor does the list exclude occupations in which a significant percentage of employees are not college graduates. For example, electricians; plumbers, pipefitters, and steamfitters; structural iron and steel workers; reinforcing iron and rebar workers; tapers; tile and marble setters; sheet metal workers; and heating, air-conditioning, and refrigerator mechanics and installers appear on the list. Overall, the occupations listed in the table accounted for 31.2 percent of employment in 2002 and are projected to account for 51 percent of the expected net gain in employment over the 2002–12 period.

The impact of education and training. As the discussion of table 10 indicated, there are a number of relatively high-paying, high-growth occupations in which the most significant source of education or training usually is not associated with the job-

holder's having obtained a 4-year college degree. An upcoming BLS publication lists, for each occupation, the most significant source of education and training generally required by employers.¹³ The same publication also gives the percentages of employees in each occupation that have a high-school degree or less, some college, or a college degree or higher. These descriptions are intended to provide general guidance, and, as a reading of the more detailed descriptions of occupations in the BLS 2004–2005 Occupational Outlook Handbook indicates, there is often a variety of educational or training pathways that enable a worker to become skilled in an occupation.

In the last two decades, several important trends in educational attainment have arisen that can have a significant impact on occupational career choices. One of these trends is that, since the late 1970s, average premiums paid by the labor markets to those with higher levels of education have increased. Certainly,

there are a number of important factors besides earnings that help to determine the career choices made by individuals. However, it is the growing distance, on average, between those with more education, compared with those with less, that speaks to a general preference on the part of employers to hire those with skills associated with higher levels of education. As shown in table 11, in 2000, on average, full-time wage and salary workers with a bachelor's degree or higher had earnings that were nearly twice those of high school graduates. This finding holds for both men and women.

Between 1994 and 2000, the supply of male college graduates increased by more than 20 percent and their real earnings rose by nearly 5 percent. (See table 11.) This willingness of the market to absorb and reward such a substantial increase in the labor

Text continues on p. 22.

¹Relatively high paying is defined as "having average annual earnings that are in the top two quartiles of the overall distribution of earnings in the 2002 Occupational Employment Survey." Fast growing is defined as "having a

projected employment change equal to or exceeding 14.8 percent, the overall average of the projections." $\,$

supply of men who have graduated from college is an indicator of the continued relative increase in the demand for workers with more education. Earnings of men with some college (including those with associate's degrees) increased by 2.4 percent, and the employment of the group grew by 13 percent. Real earnings of female college graduates rose by 4 percent, and their employment increased by nearly 30 percent. Women with some college saw their real earnings remain steady, while their employment increased by 16 percent.

THIS ISSUE OF THE MONTHLY LABOR REVIEW PRESENTS PROJECTIONS of industry and occupational employment

trends. These projections form the basis for providing career advice to individuals entering the job market, changing careers, or making further educational and training choices. Although the Bureau of Labor Statistics must judge its work against an uncertain future, a hallmark of the agency's projections is that the assumptions and model-based findings on which they are grounded are made explicit. Further, while much is known in terms of trends in economic series to date, past is not always prologue, and care must always be taken whenever projections are involved. With these points in mind, the reader will be better able to appraise and utilize the carefully thought-out content of the articles presented in this issue of the *Review*.

Notes

- ¹ Total job openings are given by the sum of net employment increases and net replacements. If employment change is negative, job openings due to growth are zero and total job openings equal net replacements.
- ² In traditional national income accounting practices, nominal gross duplicated output (also called double counting) is a measure of duplicated output, by virtue of the fact that it includes intermediate inputs which are eventually part of final output. This article uses nominal, rather than real,1996 chain-weighted gross duplicated output because adding the outputs of various industries under the latter concept does not yield total output.
- ³ Perhaps nowhere is the contrast more apparent than in the production of computers compared with the provision of computer services. The production of computers is a capital-intensive enterprise. Between 1992 and 2002, nonfarm wage and salary employment in the computer and peripheral equipment manufacturing industry fell by 24 percent, from 329,000 to 250,000. Over the same period, output in the industry grew from \$28 billion to \$263 billion (in 1996 chainweighted dollars), an increase of more than 24.9 percent per year. In the computer systems design and related services industry, employment increased by more than 161 percent, from 445,000 to 1,163,000 over the 1992–2002 period. Output also increased over the same period, at an annual rate of 8.8 percent. The Bureau projects a similar trend in the two industries over the 2002–12 period. (See Jay M. Berman, "Industry output and employment projections to 2012," this issue, pp. 58–79, table 3.)

- The material in this section was prepared both by the author and by Norman Saunders, Division of Industry Employment Projections, Office of Occupational Statistics and Employment Projections.
- ¹¹ Currently, however, there are no national surveys of occupations that provide information either on the durations of vacancies or on wage offers. The BLS Job Openings and Labor Turnover Survey estimates job openings by industry for the entire U.S. economy, and 37 States conduct job vacancy surveys that estimate job openings by occupation.

Employment outlook: 2002-12

The U.S. economy to 2012: signs of growth

Based on the assumptions used in developing economic projections, real GDP is expected to grow during the next decade, while productivity remains strong and inflation remains stable

Betty W. Su

prepares a set of projected U.S. economic factors that form the basis for the employment projections program. This article presents the projections of U.S. economic factors that underlie the 2002–12 employment projections. This set of aggregate economic projections presents some unique challenges. After the boom of the 1990s, the U.S. economy suffered a number of serious setbacks, including: the bursting of the technology bubble; the September 11, 2001, terrorist attacks; significant losses of stock market wealth; a stagnant job market; corporate accounting scandals; and uncertainties related to the war in Iraq.

Although the economy has had difficulty shaking off a stubborn slowdown, recent statistical data suggest that we are now poised for a more sustained recovery. During the 2000-02 period, the U.S. economy has experienced low inflation, low interest rates, strong productivity growth, and a healthy housing market. Also, both government monetary and fiscal policies have been focused on stimulating economic growth. Under the assumptions used by the Bureau in developing these projections, gross domestic product (GDP) is expected to reach \$12.6 trillion in chained 1996 dollars by 2012, an increase of \$3.2 trillion during the 2002–12 decade. (Also see box on page 25.)¹ This translates to an average annual rate of growth for real GDP of 3.0 percent over the period, 0.2 percentage point lower than the historical rate of 3.2 percent from 1992 to 2002. A slower growth of civilian household employment, from 1.3 percent a year during the 1992–2002 period to 1.2 percent from 2002 to 2012, is expected to result in an increase of 17.3 million employees over the latter period, still greater than the increase of 15.8 million employees over the preceding 10-year period, from 1992 to 2002. The employment projection is accompanied by an expected unemployment rate of 5.2 percent in 2012, 0.6 percentage point lower than that in 2002.

Reflecting increased globalization of the U.S. economy, foreign sectors are expected to continue their fast growing trend in the next 10 years. Besides foreign trade, gross private domestic investment also is expected to play a substantial role in the economy over the 2002–12 period. Business spending on high-tech and computer-related equipment is anticipated to lead the rapid growth. On the government side, a projected increase in defense spending reflects the long-term efforts to win the global war on terrorism and protect the American homeland.

This article begins the discussion of economic projections with the macroeconomic model and major underlying assumptions. It then examines more closely the projections of aggregate demand categories of GDP. Lastly, the Bureau's expectations for the growth of incomes, employment, and labor productivity are discussed in turn. The

Betty W. Su is an economist in the Division of Industry Employment Projections, Office of Occupational Statistics and Employment Projections, Bureau of Labor Statistics. E-mail: Su_B@bls.gov.

projections are described in the context of trends over the 2002–12 period.

The macroeconomic model

The aggregate economic projections presented in this article have been developed in the context of the macroeconomic model provided by Macroeconomic Advisers, LLC, a St. Louis, Mo, based forecasting group.² The company's quarterly model comprises 609 variables descriptive of the U.S. economy, of which 169 are exogenous assumptions—that is, variables whose values must be provided to the model in order to calculate a solution for a given period of time. Among the 169 exogenous variables, only a relatively small number of these assumptions significantly affect the long-term projections of the value of GDP and its demand makeup, as well as the level of employment necessary to produce that GDP. Those key assumptions are listed in table 1.

In addition, the projections are generally prepared with selected variables, such as the inflation rate, the level of the unemployment rate, the labor productivity growth rate, and the international trade-related issue, which are much more carefully evaluated than the other variables in the model. Setting a preliminary target value for those key variables, helps in defining the parameters around which overall projections are developed.

Major assumptions

Monetary policy. Early in 2001, just before the economy officially entered a recession,³ the Federal Reserve started easing monetary policy and cutting the Federal funds rate. Within a year, the rate was cut a total of 11 times, from 6.50 percent to 1.75 percent. In the following year, the rate fell further, to 1.25 percent in November, in response to the economic shocks accompanying the 9/11 attacks and the war with Iraq. Increasingly worried that U.S. economic growth was close to stalling, the Federal Reserve cut the funds rate again in late June 2003 to a 45-year low of 1.00 percent to help revive the economy and help prevent the economically dangerous threat of deflation.⁴

Generally, the monetary sector in the econometric model is designed to determine the money supply with a long-term steady growth. The BLS projection assumes that once growth recovers towards "trend," the Federal Reserve will reverse course and undertake monetary tightening that will push the funds rate up. By 2012, the Federal funds rate is assumed to rise to 5.33 percent, a rate close to its historical average. Bond yields will generally move parallel to the funds rate over the projection interval, but run somewhat higher. The yield on the 10-year Treasury note is expected to reach 6.25 percent in 2012. (See table 1.)

Fiscal policy. The Bureau's 10-year projections incorporate the policy impacts associated with three major tax bills enacted in the past 2-1/2 years. The first tax cuts are the immediate implementation of provisions in the "Economic Growth and Tax Relief Reconciliation Act of 2001" (EGTRRA or Economic Growth Act); the second tax cuts are the provisions of the "Job Creation and Worker Assistance Act of 2002" (JCWAA, or Job Creation Act); and the third are the recently enacted provisions of the "Jobs and Growth Tax Relief Reconciliation Act of 2003" (JGTRRA or Jobs and Tax Relief Act). The fiscal stimulus packages include reduced tax rates for individuals and on capital gains, and increases of expensing limits for certain types of investment. Although some of the provisions in the Jobs and Tax Relief Act are set to expire and return to the provisions set in the Economic Growth Act, and all of the provisions of the Economic Growth Act are scheduled to expire in 2010 and return to prior law, the model assumes that the provisions will be extended through the projection period.⁵

Tax-related assumptions affect Federal Government revenues. The Federal effective marginal personal tax rate increased from 21.3 percent of personal income in 1992 to 22.5 percent by 2002. Reflecting the recently enacted tax cut package, a gradual decrease in this rate is expected to occur over the next decade. In the BLS projections, it is assumed that the effective marginal personal tax rate will drop to 21.4 percent in 2012, noticeably lower than that in 2002. The effective marginal dividends tax rate is expected to drop significantly from 28.0 percent in 2002 to 22.5 percent in 2012, while the capital gains tax rate is anticipated to fall from 18.8 percent in 2002 to 15.0 percent in 2012. The maximum Federal corporate tax rate is assumed to be maintained at 35.0 percent in 2012; the same as in 2002.

Government spending and the budget deficit. Since 2001, Federal defense spending has increased sharply in response to the terrorist attacks of September 11 and the military operations in Afghanistan and Iraq. The acceleration of spending, together with reduced revenues due to the recent economic slowdown and legislation enacted over the past couple of years, has pushed the Federal budget from a surplus of \$207 billion in 2000 and \$72 billion in 2001 to a deficit of \$202 billion in 2002 and an estimated \$400 billion in 2003. According to the Department of Defense's current established budget plan for the next 6 years through 2009, it would require funding at higher levels than defense spending has been in any year since 1980. The budget emphasizes strong support for the global war on terrorism, sustaining high quality personnel and forces, and transforming the U.S. defense establishment.6 On the basis of Defense Department estimates, the Bureau has assumed that, after 2009, defense spending will continue the same trend toward increased levels, growing about 2 percent per year through the rest of the projection period.

The 2003 comprehensive NIPA revision

In December 2003, the Bureau of Economic Analysis (BEA), Department of Commerce, released the 2003 comprehensive, or benchmark, revision of National Income and Product Accounts (NIPA's). This latest comprehensive revision characterizes the changes in definitions and classifications, methodologies and source data, as well as changes to the tables that present the economic figures. In the comprehensive revision, the reference year for the statistical time-series data has been advanced from 1996 to 2000 for the chain-weighed-dollar estimates. The implications of those changes do not affect the projections in this issue, because the BLS projections

were completed prior to the NIPA revision. All the data presented in the 2002–12 projections are still measured on a chained-1996 dollars basis, and the historical data presented in this article are consistent with data published through the BEA's November 2003 issue of the *Survey of Current Business*, the last issue before the comprehensive revision.

Further information on the NIPA revision and the time series estimates are available in the December 2003 issue of the *Survey of Current Business*, or on the Internet at: www.bea.gov/national/2003 comprehensive revision of the National Income and Product Accounts.

In addition, the significant long-term strains on spending will begin to intensify within the next decade as the babyboom generation begins reaching retirement age. Driving those pressures on the budget will be growth in the largest retirement and health programs. Federal spending on Social Security, Medicare, and Medicaid will consume a growing portion of budgetary resources. BLS assumes that long-term defense spending on consumption and gross investment will continue to rise over the entire projection period. In short, high spending levels accompanying tax reductions will add to fiscal stimulus throughout the entire projections, but will result in budget deficits, reaching an estimated \$164 billion in nominal terms in 2012. (A further discussion is presented later in the "Federal Government" section.)

Energy. Among the energy-related assumptions, the most important is the refiners' acquisition price for crude oil, expressed in dollars per barrel. Growing concerns about a U.S. confrontation with Iraq and wider disruptions to Gulf supplies drove U.S. crude oil over \$40 per barrel in February 2003, approaching the \$41.15 record set during the buildup to the 1991 Gulf War. Although oil prices dropped after the U.S. attacked Iraq, with little disruption to Middle East crude flows, energy prices are still on the high side.

In the aggregate economic model, the level of GDP determines the level of energy demanded by the economy; the price of crude oil determines the level of domestic production, and the residual amount of the energy demand not met by domestic production is, by assumption, met by imports of crude petroleum. This particular assumption is drawn from annual energy projections prepared by the U.S. Department of Energy, which expects the dollar value of a barrel of crude oil to rise from about \$23.61 per barrel in 2002 in nominal terms to \$30.52 per barrel in 2012. The domestic share of crude-oil production is expected to continue to decline from 54.6 percent

of total U.S. demand in 1992 and 39.5 percent in 2002 to 31.2 percent by 2012.⁷

Demographic assumptions. The demographic assumptions are based on the 2000 Census middle-series population projections. These projections estimate the U.S. population to be expanding at an annual rate of 0.9 percent between 2002 and 2012, when the population reaches 315 million. Growth in the older age cohorts will be strong as baby boomers age. The BLS labor force projections are consistent with the Census Bureau population projections and are prepared at detailed levels as well as for the aggregate; the estimates then carry over to the aggregate economic model.8

Inflation. After accelerating in the 1970s and early 1980s, inflation has slowed significantly in recent years. Combined with high productivity, relatively cheaper imports, and the absence of commodity shocks, even during a long-lived expansion in the 1990s, changes in the labor market prevented any significant acceleration of wages. While wage pressures remained remarkably modest, inflation remained moderate.

Monetary policy remains important in the long-term projections, not so much in determining the level of output, but rather in determining the rate of inflation. With a steady-state rate of inflation in mind, it is assumed that the Federal Reserve will attempt to keep inflation contained over the projection period while providing adequate money growth to fuel economic expansion. The rate of inflation, as measured by the chainweighted GDP price index, will grow at an average rate of 2.2 percent per year over the projection horizon.

Unemployment rate. During the recession of 2001, the unemployment rate rose from a 30-year low of 4.0 percent in 2000 to 4.7 percent in 2001 and jumped further to 5.8 percent in 2002. The unemployment rate reached an 8-year-high of 6.0 percent in

2003. However, the model assumes that long-term economic growth and job recovery will gradually push the unemployment rate down over the projection period. Keeping the labor force projections with steady inflation in mind, by the end of the projection interval, the economy is expected to make a transition towards "full employment." This underlies the expected unemployment rate of 5.2 percent in 2012. (A further discussion is presented later in the "Employment" section.)

Productivity growth. It is the economy's ability to increase supply in the face of increasing demand over the long run that determines its potential growth path. Growth in aggregate supply depends on the increase in the labor force, the growth of the capital stock, and improvements in productivity. In general, productivity is a cyclical variable that typically falls during recessions because both labor and capital are underutilized as output sags or grows more slowly. Surprisingly, productivity

never declined during the most recent economic downturn. Better still, acceleration has continued even as investment in information technology has fallen from its late-1990's peak. Productivity has increased at its fastest pace of more than 3.0 percent annually over the 2000–02 period, compared with 2.5 percent yearly from 1995 to 2000 and 1.4 percent from 1973 to 1995.

It is unclear to what extent the continued rise is due to unusual cyclical factors and to what extent the rise reflects a further increase in underlying structural productivity. It is clear that productivity growth is the main influence on long-term growth and living standards. The projections assume that productivity will keep close to its previous 10-year trend and grow at an average of 2.1 percent per year during the projection period. The increase is consistent with a projected faster growth of the capital stock and capital services, as well as more capital deepening over the same projection horizon. (A further discussion is addressed in the "Productivity" section.)

International trade. The trade deficit has widened and the current account deficit has deteriorated significantly since 1998. The U.S. trade deficit reached \$424 billion or 4.1 percent of GDP in 2002, a record in nominal dollars and as a percentage of gdp. Slow economic growth abroad has continued to depress the growth of U.S. exports, as the economies of many major European countries are still struggling toward recovery and as Japan lags behind U.S. growth. In addition, the drop in the U.S. dollar since 2002 is still modest on a trade-weighted basis. In the long run, the greatest uncertainty lies with potential export growth, depending as it does on growth in the economies of major U.S. trading partners in the European Community and in the Pacific Rim countries. The dollar will have to depreciate steadily against foreign currencies in order to keep the U.S. current account deficit from growing too fast. Over the next decade, the projection contemplates that the exchange rate will drift downward over the projection period. A trade deficit in goods will still exist throughout the entire projections, while a surplus in services will continue to improve. (A detailed discussion on exports and imports is described in the "exports and imports" section.)

In sum, the projections anticipate a growth economy, including a steady expansion of the labor force, strong productivity growth, a favorable outlook regarding inflation, and opportunities for jobs.

Aggregate demand GDP

After the late-1990's boom, the U.S. economy began to slow down in the middle of 2000, with a recession taking place in 2001. During the 3-year period ending in mid-2003—a period including the burst of the stock market bubble, the shock of 9/11, corporate accounting scandals, and uncertainties associated

with the war in Iraq—the U.S. economy struggled with below-trend real growth at an annual average of roughly 1.6 percent from 2000 to the second quarter of 2003. The path of growth was insufficient to keep the unemployment rate from continuing to rise, in part because of the hefty growth of productivity, which enables companies to get more output from fewer workers. During this period, consumer spending was moderate, inventory accumulation was slow, business investment was sluggish, foreign trade deficits were wide, and only defense spending was growing with any real strength. In the second half of 2003, however, statistics indicate a sharp increase in output, providing significant evidence that the U.S. economy has begun to strengthen. As mentioned earlier, over the long term, real gdp is projected to grow at an average annual rate of 3.0 percent per year over the 2002–12 span.

Personal consumption expenditures. Spending by consumers, which makes up two-thirds of economic activity, is the largest component of demand. During the past four decades, the growth of consumer spending reflected the interaction of many factors that influenced consumers' decisions. Among those particularly important factors were: increasing affluence, changing demographics, technological innovations, and changing tastes and lifestyles. Affected by the wave of baby boomers moving through the population beginning in the 1960s, consumer spending grew from an average of 2.5 percent yearly between 1972 and 1982 up to 3.4 percent over the latter 10-year period, from 1982 to 1992. Rising disposable incomes during these periods supplied the resources necessary to support the expansion in consumption. As consumers got into the spending habit, however, increases in personal consumption were more often made at the expense of the savings rate, which dropped from a high of 10.9 percent in 1982 to 8.7 percent by 1992. (See tables 2 and 3.)

| Savings rate (percent) | 10.9 | 8.7 | 3.7 | 2.3 | _ | - | - | - | -2.3 | -8.3 | -4.4 |

Beginning in 1996, with consumers buoyed by a number of factors, including the thriving job market, steady incomes, low interest rates, low inflation, and increased wealth from rising asset prices, spending accelerated to its fastest pace in more than a decade. Consumption expenditures grew by 4.4 percent yearly from 1996 to 2000. Mirroring the expansion in consumption, the annual savings rate dropped sharply to 2.8 percent in 2000.

Beginning in late 2000 and continuing until mid-2003 (a period including the 2001 recession and the war in Iraq), consumer purchases of goods and services still managed to remain at a rate of growth about 2.7 percent annually between 2000 and the second quarter of 2003. This divergent trend suggests that the uncertainties associated with the war may have put a dent in consumer spending, but only had a limited impact on spending. Gains from Federal tax cuts and mortgage refinancing probably remained key factors behind the willingness of consumers to continue spending.

Over the next decade, consumer demand is projected to grow at an average annual rate of 2.8 percent from 2002 to 2012, sliding down from the historical high of 3.7 percent rate posted during the preceding 10-year period. The 2.8 percent rate is in line with, but less than the projected 3.0 percent growth for GDP over the

same span. Real disposable income is projected to grow at a 2.6-percent annual rate between 2002 and 2012, 0.5 percentage point lower than the rate for 1992–2002.

At a finer level of detail, consumer spending on durable goods, especially for cars and light trucks, was most notable during the past 3 years. Sales of autos roared to a peak of 17.2 million units in 2000, as the value of sales incentives reached a new high and buyers responded eagerly to the incentives. The long-term outlook for motor vehicle sales will call for a slowdown in the rate of increase relative to past performances, and the solid gain in auto sales is expected to ease. Total light-vehicle sales are anticipated to stay at 16.6 million units in 2012. Although the number of vehicles per person has increased significantly in the past 20 years, the United States might be approaching a saturation point in the rate of vehicle ownership. Future growth in vehicle sales will be primarily driven by growth in population and demand for replacement vehicles. Demand for motor vehicles and parts is projected to grow at a rate of 2.0 percent yearly between 2002 and 2012, compared with 5.4 percent in the 1992– 2002 period. (See table 4.)

Among consumer purchases of services, a major contributor to growth is health care expenditures. The growing

number of elderly in the population, as well as advances in medical technology, has resulted in a greater demand for health services. Spending on medical services increased 2.5 percent per year during the 1992–2002 period. Over the coming 10 years, due to the importance of the demographic factors, spending on medical services is expected to continue to post solid gains at a growth rate of 3.0 percent annually.

Gross private domestic (business) investment. This component of GDP consists of business spending for equipment and software, ¹⁰ purchases of nonresidential structures, purchases of residential structures, and changes in business inventories. Historically, private business investment is one of the most volatile

Source: Historical data-Bureau of Economic Analysis; projected data-

elements of final output, responding to the business cycle and to shifting interest rates and inflation. During the recessions of the 1980s and 1990s, business investment experienced a sharp decline. Nevertheless, a strong economy boosted investment to a historical high in 2000, making an average growth of 8.8 percent per year since 1992, compared with a growth in investment of 3.9 percent between 1982 and 1992. (See table 5.)

However, during the 2000–02 period, nonresidential investment was one of the weakest segments of demand in part because of over-investment in Internet gear and other information-technology equipment during the boom of the late 1990s. Spending on equipment and software, the largest category of business investment, plummeted 8.0 percent between 2000

most detailed lines.

and 2002. In contrast to the softness in nonresidential investment, residential investment grew briskly. Propelled by record low mortgage rates and also by the continued growth in housing demand, the housing market has been on a nearly unbroken upward trend for the 3 years ending in 2002. Residential construction rose 5.4 percent during the 1999–2002 period, while housing starts reached a 16-year high of 1.71 million units in 2002.

As already noted, the recent data show that beginning in the second half of 2003, the economy is showing signs of recovery, but in addition, capital spending is turning up. Over the next decade, with good profitability, technological innovation, and solid demand growth, the projections indicate nonresidential investment in equipment and software will grow at a robust rate of 7.9 percent per year from 2002 to 2012. Purchases of non-residential structures are expected to grow slightly faster than the historical pace: 1.8 percent annually over the projection period, compared with a lackluster investment of 1.4 percent growth between 1992 and 2002.

Although interest rates clearly influence the short-term timing of home purchases, demographics are the primary determinant of long-term housing activities. As the 35- to 44-year-old population is estimated to decline by 2012, traditionally thought of as the prime home-buying age group, demand for fixed residential investment is projected to retreat and settle down after its 2002 record high. A still healthy 2.1-percent average annual growth rate is projected over the 2002–12 period, while housing starts are expected to rise modestly to 1.79 million units in 2012, from 1.71 million units in 2002. In sum, business investment as a whole is expected to be a great

contributor to U.S. economic growth over the next decade, at a rate of 5.5 percent per year for the 2002–12 period.

Exports and imports. Globalization and international competition have played an important role in U.S. economic activity. During the 1990s, increasing exports drove GDP growth. So did imports: The strong U.S. dollar and falling foreign commodity prices in emerging markets helped keep the Nation's inflation low and combined with other factors to trigger strong growth in consumer spending. However, increased globalization has also brought new challenges to the U.S. economy, including a widening of the trade deficit in total goods and services. The trade deficit ballooned to a record \$423.6 billion in 2002 in nominal terms, or \$488.5 billion in real dollars, up from the 1992 figure of \$27.8 billion in nominal terms, or \$19.8 billion in real dollars. In terms of growth rate, while exports increased at a 7.5-percent annual rate from 1982 to 1992, imports grew 7.4 percent. Over the 1992-2002 period, exports posted a 5.0-percent rate of growth annually and imports soared faster at 8.7 percent. (See table 6.)

In any long-term projection program, the international trade sector is the most difficult to predict. The key to the Bureau's 10-year outlook for U.S. trade is the increase in global accessibility and the rise in international competition. With the world assumed to become more open to trade, the share of GDP accounted for by both exports and imports is expected to grow apace. A continued decline in the exchange rate will stimulate U.S. exports abroad and increase international competitiveness. Real exports are expected to grow at a 5.7-percent annual rate between 2002 and 2012. Both exports of goods and services also are expected to

²The residual following the detail categories for "imports is the difference between the aggregate of imports of goods and services," and the sum of the

grow at the same rate of 5.7 percent annually per year during the projection period.

Imports are projected to grow at a rate of 5.2 percent annually over the 2002–12 projection period, much lower than the 8.7 percent annual rate of growth for imports over the 1992–2002 span. Imports of goods are expected to grow at 5.6 percent per year, and a 3.6-percent annual rate of growth is projected for imports of services during the 2002–12 period. As a result, net exports (exports minus imports) are projected to continue to make a negative contribution to the aggregate demand, reaching \$734.6 billion in real terms by 2012. Although the Bureau projects a continued increase in the trade surplus in services, the surplus in services still cannot offset the even larger deficit in goods.

The most troubling question, which arises from the foreign trade projections, is how long can the flow of funds out of the United States, to pay for high imports, continue until financial markets begin to feel the pinch? Clearly, increasing interest rates over the period will help slow domestic demands on financial markets, and the sustained Federal budget deficit will also help offset financial outflows to foreigners. Nonetheless, the share of nominal GDP accounted for by the current account deficit jumped sharply between 1999 and 2002, moving from a more traditional 2-percent share to a 5-percent share, in absolute terms.

Owing to steady pressure from the current account deficit, the dollar is projected to depreciate throughout the entire forecast period. However, the current account deficit will continue to grow, reaching just more than 7 percent of nominal GDP by 2012. With such a burden, presumably the U.S. current account deficit can be financed by large inflows of private capital, as investors find U.S. assets to be some of the most attractive in the world. In one sense, the widening deficit is a product of the desire of foreign investors to get in on the action in the U.S. economy. Nevertheless, the United States will have to face the risks that the stock of U.S. indebtedness to the rest of world will grow even more rapidly, and net factor payments from the United States to the rest will also increase rapidly.

Federal Government. During most of the 1980s and the 1990s, the Federal Government faced a large deficit. The question of how to reduce that deficit was a centerpiece of discussion among economists and policymakers for more than 20 years. In nominal terms, the deficit grew from \$132.6 billion in 1982 and peaked at \$297.6 billion in 1992. Between 1993 and 1997, the deficit grew steadily smaller. After 28 years of deficits, in 1998, the budget recorded a substantial surplus of \$43.8 billion as a result of a strong bipartisan effort to control spending by the Federal Government. The surplus increased further during the 1999–2001 period, from \$111.9 billion in 1999 up to \$206.9 billion in 2000, but declined to \$71.9 billion in 2001 as growth began to cool and the tax cuts of 2001 began to enact. The surplus accounted for 2.1 percent of nominal GDP in 2000, its largest share of GDP during the

past four decades. This dramatic change is attributable to an increase in tax receipts from an expanding economy, on the one hand, and a decline in expenditures due to the Balanced Budget Act of 1996, on the other.

However, since late 2001, as noted earlier, Federal defense spending has increased sharply in response to the terrorist attacks of September 11 and to military operations in Afghanistan and Iraq. On the revenues side, falling receipts from individual and corporate income taxes due to the recent economic slowdown as well as the result of tax policy, accounted for almost all the decline in total receipts over the 2000–02 period. In 2002, total receipts were 17.9 percent of GDP, down substantially from the post-World War II peak of 20.7 percent reached in 2000. The acceleration of defense spending and the reduction of Federal revenues have pushed the Federal budget to a deficit of \$202 billion in 2002 and an estimated deficit of \$400 billion in 2003.

The macroeconomic model assumes that Federal budget deficits will remain through the projection period, reaching \$164.1 billion by 2012, or accounting for 0.9 percent of GDP. The projections also anticipate shifts in the composition of Federal expenditures over the 2002-12 period. Transfer payments (primarily Medicare and Social Security) are projected to account for a 43.9-percent share of Federal expenditures by 2012, declining from 44.9 percent in 2002. Despite this deceleration, Medicare service will make up an increasingly larger proportion of Federal expenditures. Within the next 10 years, the large baby-boom generation will begin to reach retirement age and become eligible to receive Medicare benefits. In addition, advances in medical technology will probably keep pushing up the costs of providing health care. Underlying the demographic changes anticipated for the next decade, spending for Medicare and Social Security together will account for a 35.3-percent share of Federal expenditures by 2012, up rather substantially from 29.2 percent in 1992 and 33.7 percent in 2002. Similarly, the share of grants-in-aid (primarily Medicaid) is projected to increase to 15.8 percent, rising from 10.5 percent in 1992 and 14.7 percent in 2002. (See table 7.)

Real defense spending (which includes expenditures for military compensation, defense capital goods, and gross investment in equipment and in structures¹²) declined absolutely over the 1988–98 period, as the military's compensation was reduced and purchases of weapons were postponed. Cuts also entailed retiring some older equipment without replacing it. In 1999, however, real spending on defense reversed its 10-year trend and started to rise slightly, due mainly to increases in consumption of capital goods and investment in equipment and software. After the September 11 terrorist attacks, defense spending has expanded in response to the perceived threat of terrorism and homeland security protection. Clearly, the surge in military spending is

driven by the high costs of war with Iraq and post-war reconstruction. On the basis of Defense Department estimates, BLS has assumed that military force levels will remain fixed at 1.5 million troops through the projection period. The budget provides funds for programs that sustain high quality people and forces. As a result, real defense spending is projected to grow at an average annual rate of 2.5 percent from 2002 to 2012, reaching \$510.2 billion in the latter year. (See table 8.)

Real nondefense spending for government, which accounts for the spending on salaries of Government employees and on administrative expenses of all Federal nondefense programs, is assumed to increase at a slower pace of 1.1 percent per year between 2002 and 2012, compared with its 1.8 percent annual rate of growth between 1992 and 2002. (See table 8.) This assumption leads to a projected nominal growth, averaging 4.1 percent per year for all nondefense spending between 2002 and 2012, below the 4.5-percent annual growth from 1992 to 2002. (See table 7.)

State and local governments. Real spending by State and local governments is projected to increase 1.4 percent annually from 2002 to 2012—much lower than the 3.0-percent rate of growth posted for the 1992–2002 period. (See table 8.) In nominal terms, State and local government receipts of grants-in-aid from the Federal Government for Medicaid and other programs assume to reveal the same trend toward

increased levels, representing 24.9 percent of State and local revenues in 2012, up from 19.3 percent in 1992 percent and 23.4 percent in 2002. (See table 9.) This translates to an average annual rate of growth of 6.4 percent from 2002 to 2012, well above the growth for most of other categories of revenues during the same period. Still, the 6.4 percent figure represents a decline from the category's 7.4 percent annual rate of growth over the 1992–2002 period.

On the expenditures side, consumption expenditures are expected to continue to account for the largest component of total State and local spending in 2012, but their share of total spending is projected to decline from 77.4 percent in 1992, 76.3 percent in 2002, and to 69.8 percent in 2012. In contrast, an increased level of transfer payments, due to the increases in Medicaid services and retirement pensions, is expected to keep the share of transfer payments rising, from 23.2 percent in 1992 and 24.7 percent in 2002 to 31.1 percent in 2012. In sum, State and local governments will run surpluses throughout most of the projection period; statutorily, nearly every State is required to do so, as their expenditures are tied closely to their available revenues.

Income

From 1992 to 2002, the portion of labor income in total personal income declined slightly. However, wage and salary dis-

bursements in the private sector, the largest segment of labor income, increased noticeably as a share of total personal income, from 55.3 percent in 1992 to 56.0 percent in 2002. The projections anticipate that this increasing trend in wages and salaries will continue through the projection period, reaching 57.3 percent in 2012. (See table 3.)

Over the same period, another major component of personal income, business-related personal income, including proprietors' income, personal dividends, interest income, and rental income, increased moderately from a 26.6-percent share in 1992 to 27.0 percent in 2002. However, this type of income is projected to fall to a 24.4-percent share in 2012. Substituting the decline in importance of business-related personal income, transfer payments have become an increasingly substantial source of personal income over the past decade. Between 1992 and 2002, transfer payments rose as a share of personal income from 13.9 percent to 14.4 percent. The Bureau projects this category will continue to rise until it accounts for 15.6 percent in 2012, reflecting both rising per-capita medical costs and an increase in the older population, the most likely users of Medicare programs. In short, the share of labor income in total personal income is expected to increase substantially, from 62.8 percent in 2002 to 64.8 percent in 2012.

Traditionally, personal consumption is the largest component indicating how people spend their incomes, and its share of income expenditures has increased over time. The projections anticipate that the historical trend will continue and the share will rise to 82.9 percent of personal income in 2012, up from 78.1 percent in 1992 and 81.9 percent in 2002. However, the trend of increased consumption is projected to result in a very low personal savings level in 2012.

Nevertheless, on a per capita basis, nominal disposable income is projected to increase at an average annual rate of 4.3 percent from 2002 to 2012, reaching a level of \$41,459 in the latter year; a gain of more than \$14,200 over the projection span. In real terms—that is, chained 1996 dollars—per capita income is projected to grow 1.7 percent per year from 2002 to 2012. Accordingly, real standard of living would rise over the projection period, at least measured on the basis of growth of disposable personal income.

Employment

After the 1990–91 recession, there followed 9 years of economic expansion, resulting in year-to-year decreases in unemployment and increases in employment; both of which occurred through the rest of that decade. Unemployment fell for 8 straight years, from 7.5 percent in 1992 to 4.0 percent in 2000, the lowest reading in 30 years. That trend expanded employment by 16.7 million people over the period. Conversely, even 2 years after the mild

2001 recession, job growth showed very slow progress. However, the continued recovery in output and continued strong demand is expected to catch up with the robust growth in productivity and lead to sustained job growth. Under the assumption of long-term economic stability, the BLS model assumes a return to more normal levels of job creation in the future. In 2012, a 5.2-percent unemployment rate is projected. (See table 10.)

Overall, civilian household employment is projected to increase by 1.2 percent per year from 2002 to 2012. The result is that about 17.3 million employed persons will be added to the economy over the 10-year projection period. Total employment measured on a nonfarm establishment basis is projected to grow at a rate of 1.6 percent between 2002 to 2012, from 130.4 million to 152.1 million, an increase of 21.7 million jobs.¹⁴

The civilian labor force is projected to grow at a rate of 1.1 percent per year from 2002 to 2012; the same as that attained over the preceding 10-year period. This translates into an increase of 17.4 million over the projection span. The Census Bureau projects that the total U.S. population will increase at a 0.9-percent rate of growth annually over the 2002–12 period; the same rate of increase as that between 1992 and 2002. The Census Bureau also estimates that the population aged 16 and older will increase at a rate of 1.1 percent over the projection span; 0.1 percentage point higher than the rate of growth in the earlier period. ¹⁵

Productivity

Productivity, measured as output per hour in the private nonfarm business sector, has demonstrated very strong gains since 1995. As mentioned earlier, even during the past 3 years of economic weakness (a period that included a recession and a recovery), labor productivity grew at an annual average rate of more than 3 percent between 2000 and 2002; somewhat higher than the annual rate of 2.5 percent from 1995 to 2000 and much higher than the 1.4 percent trend from 1973 to 1995. This growth, moreover, has occurred, despite a deep decline in nonresidential investment spending since 2001. In fact, economic data suggest that almost none of the acceleration in productivity after 1995 is due to adjustments for responses to the business cycle experienced in the historical period of 1973–95.

How is one to interpret this truly extraordinary performance since 1995? Cyclical forces probably played some role, but efficiency gains likely were facilitated by the best use of important new technologies. Adjusting to new technologies takes time, and it is plausible that the adjustment process has continued to boost productivity growth in recent years. More fundamentally, the trend in productivity growth has ratcheted up, and this development has been the driving force behind the recent exceptionally high rate of growth.¹⁷

| (billions of chained 1996 dollars) | 26.3 | 31.9 | 39.1 | 39.1 | 47.9 | 2.0 | 2.0 | 2.1 |

Over the next 10 years, it is uncertain whether the structural productivity growth that emerged in the past will continue or if the late 1990's dramatic productivity surge will be repeated, but some high levels of productivity are foreseen. Over time, the faster productivity growth will mean a higher standard of living, with most of the productivity gain eventually taking the form of higher real wages. The Bureau anticipates that

productivity will grow at a rate of 2.1 percent per year over the 2002–12 period, virtually the same as that recorded between 1992 and 2002. This expected solid productivity growth in the aggregate economic projections is consistent with the strong growth of capital stocks, resulting from the projected rates of business investment, especially in efficiency-enhancing equipment and computer software.¹⁸

Notes

operates and simulates on a Windows-based software program called WUMMSIM.

¹ In this article, discussions of GDP and its final demand components are couched in terms of real values unless otherwise noted. Real GDP and its components are stated in 1996 chain-weighted dollars. Chain weighting replaces the past practice of computing those indicators by reference to fixed base-year prices with an averaging technique. The chain-weighted methodology calculates the prices of goods and services in order to use weights that are appropriate for the specific periods or years being measured. As a result, for a particular year, the most detailed GDP components do not add up to their chain-weighted aggregates, and the chain-weighted aggregates do not add up to the chain-weighted real GDP For more details, see J. Steven Landefeld, Brent R. Moulton, and Cindy M. Vojtech, "Chained-Dollar Indexes, Issues, Tips on Their Use, and Upcoming Changes," Survey of Current Business, November 2003, pp. 8-16. It should be noted that in the Bureau of Economic Analysis' latest released comprehensive revision of National Income and Product Accounts (NIPA's), the reference year has been changed from 1996 to 2000 for the chainweighted-dollar estimates. All data presented in this article are still measured on a chained-1996 dollars basis because the BLS projections presented in this issue were completed prior to the NIPA revision.

² For the first time, the macroeconomic model developed by the Macroeconomic Advisers, LLC forecasting group, is used to prepare the 2002–12 aggregate economic projections. The Macroeconomic Advisers firm developed and supports the Washington University Macro Model, which the Macroeconomic Advisers team uses as a central analytical tool for the short-term and long-term forecasts of the U.S. economy. The macro model is a quarterly econometric system of 609 variables—440 equations and 169 exogenous variables. It

³ The Business Cycle Dating Committee, National Bureau of Economic Research, determined in July 2003 that the 2001 recession began in March 2001 and ended in November 2001. This 8-month recession is slightly shorter than the average duration of recessions of 11 months since World War II.

⁴ The Federal Reserve cut the funds rate 11 times during the year 2001, from 6.50 percent to 1.75 percent. It then held the rates steady through most of 2002, until a half-percentage-point cut in November. A further reduction occurred in June 2003 that lowered the funds rate by another 25 basis point to 1.00 percent, the lowest rate since 1958.

⁵ The tax provisions of the "Economic Growth and Tax Relief Reconciliation Act of 2001" came just after the economy had entered into the 2001 recession. It lowered marginal tax rates for all taxpayers. Its immediate tax relief in the summer and the fall of 2001 boosted consumer demand and helped to ensure the recession was short and shallow. The major tax provisions will expire in 2010. The tax provisions of the "Job Creation and Worker Assistance Act of 2002" provided incentives for business investment to jump-start the recovery, along with extended unemployment benefits for individuals who remain unemployed as a result of the 2001 recession. The tax provisions of the "Jobs and Growth Tax Relief Reconciliation Act of 2003," enacted as an extended plan to speed up the 2001 tax cuts, strengthen the economic recovery, and accelerate job creation from its current slow pace. The Macroeconomic Advisers model, assumes

that nearly all of the provisions of the Jobs and Growth Tax Relief Reconciliation Act and the Economic Growth and Tax Relief Reconciliation Act are permanent.

- ⁶ The Department of Defense spending and force-level estimates through the year 2009 are published in National Defense Budget Estimates For FY 2004 (Office of the Under Secretary of Defense (Comptroller), March 2003). For a brief description of the budget, see, "Fiscal 2004 Department of Defense Budget Release," No. 044-03 (Department of Defense, February 03, 2003).
- ⁷ Each year, the Energy Information Administration of the Department of Energy publishes a range of estimates regarding energy supply and demand over the coming 20 years. The Bureau's energy assumptions for nominal world oil prices are based on the Department of Energy results. See "Annual Outlook 2003 with Projections to 2025" (U.S. Department of Energy, Energy Information Administration, January 2003). The real imported oil prices are derived from their nominal prices, deflated by the GDP chain-weighted deflators.
- ⁸ For a further discussion of labor force projections, see Mitra Toossi's article in this issue, pp. 37-57.
- 9 In November 2003, the Department of Commerce reported that the economy grew at a robust 8.2-percent annual rate in the third quarter of 2003 as a result of strong increases in consumer spending, business investment, housing construction, and exports. It was the highest growth rate since the first quarter of 1984, but job creation continued to lag.
- ¹⁰ In December 1999, The National Income and Product Accounts recognized business expenditures for computer software as investment. Previously, only software embedded in equipment by the producer of that equipment was counted as investment. Business purchases for own-account production (that is, software produced by a business for its own use) were classified as inputs to production. For further reading and information, see "A Preview of the 1999 Comprehensive Revision of the National Income and Product Accounts: Definitional and Classificational Changes," Survey of Current Business, August 1999, pp. 7-20, and "Improved Estimates of the National Income and Product Accounts for 1959-98, Results of the Comprehensive Revision," Survey of Current Business, December 1999, pp. 19-37.
- 11 The Congressional Budget Office closed its books in the fiscal year 2003 that ended September 30. The deficit for fiscal 2003 was \$374 billion; \$27 billion less than the CBO forecast in August 2003. In this article, the budget surplus or deficit is measured in calendar year and on the National Income and Product Accounts basis.
- 12 In January 1996, The National Income and Product Accounts recognized government expenditures on equipment and structures as investment. Accordingly, government purchases are now divided into consumption expenditures and gross investment. This approach treats government purchases of fixed assets in a manner more symmetric to the treatment of such assets in the private sector. For more details, see "Preview of the Comprehensive Revision of the National Income and Product Accounts: Recognition of Government Investment and Incorporation of a New Methodology for Calculating Depreciation," Survey of Current Business, September 1995, pp. 33-41. In December

- 1999, The National Income and Product Accounts reclassified government purchases of own-account production of software (that is, software produced by a government agency for its own use) from government consumption expenditures to gross government investment. This shift has no effect on GDP. (See footnote 10 for further readings.)
- In November 2003, the U.S. Congress approved an \$87.5 billion spending package for U.S. military operations and aid in Iraq and Afghanistan. It is the second major special funding bill for Iraq and for combating terror that President Bush has requested and Congress has produced in less than 7 months. In April 2003, a \$78.5 billion package was enacted that included \$62.4 billion for war costs and \$7.5 billion for Iraqi relief and reconstruction. Also see footnote 6 for a discussion of defense spending and military force-level estimates.
- ⁴ Employment on a household basis, the concept of employment used in the aggregate economic projections discussed in this article, is a count of persons who are working or actively seeking work. The historical estimates for household employment are derived from the Current Population Survey, a survey carried out for the Bureau of Labor Statistics by the U.S. Bureau of the Census. The concept of employment on an industry level of detail, discussed elsewhere in this issue of the Review, is a count of jobs and is based on an establishment-level survey called the Current Employment Statistics survey. Since 1994, these two measures have diverged sharply. For an explanation of the increase in this employment gap, see Thomas Nardone, Mary Bowler, Jurgen Kropf, Katie Kirkland, and Signe Wetrogan, "Examining the Discrepancy in Employment Growth between the CPS and the CES," a paper prepared for the presentation to the Federal Economic Statistics Advisory Committee on October 17, 2003.
- ¹⁵ Population and labor force estimates from 2000 reflect the results of Census 2000 adjustments. The new weighting procedures resulted in the higher population estimates and higher civilian labor force figures due to a major reevaluation of the international migration estimate. Data from 2000 are not strictly comparable with prior years because the revisions did not weighted back to the previous years. For this reason, data before 2000 are still on the 1990-based estimates. For a further discussion of population and labor force projections, see Mitra Toossi's article in this issue, pp. 37-57.
- ¹⁶ Productivity, measured as output per hour in the private nonfarm business sector, increased by 5.4 percent annually from 2001 to 2002. In 2003, productivity growth registered 7.0 percent in the second quarter and 9.4 percent in the third quarter, the best performance in 20 years.
- ¹⁷ See "Productivity Growth: A Realistic Assessment," remarks by Vice Chairman Roger W. Ferguson, Jr. (The Federal Reserve Board, at the Stockton Lectures 2002, London Business School, London, U.K., Oct. 24, 2002); and "Recent Experience and Economic Outlook," remarks by Vice Chairman Roger W. Ferguson, Jr. (The Federal Reserve Board, at the 2003 Global Economic and Investment Outlook Conference, Carnegie Mellon University, Pittsburgh, Pennsylvania, Nov. 12, 2002).

Employment outlook: 2002-12

Labor force projections to 2012: the graying of the U.S. workforce

The labor force will continue to age, with the annual growth rate of the 55-years-and-older group projected to be nearly 4 times that of the overall labor force; as the participation rates of older age groups increase, the older population's share of the workforce will rise

Mitra Toossi

his article examines projected trends in the labor force over the 2002–12 period. By 2012, the number of persons working or looking for work is expected to reach 162.3 million. The labor force is anticipated to exhibit steady growth and increase by 17.4 million, or 12 percent, over the 2002 figure. The growth in the labor force during 2002–12 is projected to be larger than in the previous 10-year period, 1992–2002, when the labor force grew by 14.4 million, or 11.3 percent.

The annual rate of growth in the women's labor force is expected to remain the same as it was during the 1992–2002 period, namely, 1.3 percent, but it will still increase at a faster rate than that of men. (See table 1.) The men's labor force is expected to grow at an annual rate of 1.0 percent, more rapidly than the growth rate in the 1992–2002 period, even though the aggregate labor force participation rate for men is projected to continue to decline. Women's share of the labor force is expected to increase from 46.5 percent in 2002 to 47.5 percent in 2012. By contrast, men's share is projected to decline from 53.5 percent in 2002 to 52.5 percent in 2012.

The projected labor force growth will be affected by the aging of the baby-boom generation—persons born between 1946 and 1964. In 2012, the baby-boom cohort will be 48 to 66 years. This age group is expected to show sig-

nificant growth over the 2002–12 period. The labor force will continue to age, with the annual growth rate of the 55-and-older group projected to be 4.1 percent, nearly 4 times the rate of growth of the overall labor force. It is anticipated that, in 2012, youths will constitute 15 percent of the labor force, and primeage workers—those between the ages of 25 and 54—will make up about 66 percent of the labor force. The share of the 55-and-older age group will increase from 14.3 percent to 19.1 percent of the labor force.

As a result of divergent rates of population growth in the past, racial and Hispanic-origin groups are projected to continue to show widely varied rates of growth. By 2012, due to faster population growth resulting from a younger population, higher fertility rates, and increased immigration levels, the Hispanic labor force is expected to reach 23.8 million. Despite slower-than-average growth, white non-Hispanics will continue to make up about 66 percent of the labor force.

Every 2 years, the Bureau of Labor Statistics produces medium-term, or 10-year, labor force projections. The present set of projections covers the 2002–12 period and estimates the future size and composition of the labor force. The labor force projections are used as input in projecting the industrial and occu-

pational employment patterns of the U.S. economy.

The labor force projections are estimated by combining population projections calculated by the U.S. Census Bureau with the labor force participation rate projections developed by the Bureau of Labor Statistics.² Consequently, the labor force is a reflection of changes in either the population trend or the labor force participation rate. Changes in the labor force are better understood if they are decomposed into these two components, each of which is therefore discussed separately in what follows.

Population projections

The population projections provided to the Bureau of Labor Statistics by the Census Bureau for this round of projections were based on the 2000 census of the U.S. population (hereafter referred to as Census 2000; see box on this page). The Census Bureau makes several alternative population projections based on different assumptions about future fertility, mortality, and migration. The Bureau of Labor Statistics selects the middle-series scenario of the population projections as a basis for its labor force projections. The main assumptions of the middle series are as follows:

• The level of childbearing among women is assumed to remain close to the present levels, with differences by race and Hispanic origin diminishing over time.

- Mortality is assumed to decline gradually, with less variation by race and Hispanic origin than at present.
- · International migration is assumed to vary over

Census 2000 and the U.S. population

Census 2000 counted 281.4 million people in the United States, a 13.2-percent increase over the 1990-census population of 248.7 million. Numerically, the increase was 32.7 million, the largest between two censuses. In April 1999, the Census Bureau had estimated that the U.S. population would reach 274.6 million in 2000. Although the difference between the estimates and the projections—the so-called error of closure—was a considerable 6.8 million, Census 2000 resulted in a more accurate count and higher population controls for all racial, sex, age, and ethnicity categories. According to Census 2000, the number of Hispanics had grown substantially from the previous census, making Hispanics the largest minority in the U.S. population. This higher population count was reflected most significantly among Hispanic men and in the younger age category of 18 to 29 years. (More information is available on the Census Bureau website, http://www.census.gov/population/www/ projections/popproj.html.)

¹ Data for 1982 and 1992 represent the "Asian and other" category with 1990 census weights. Data for 2002 with 1990 census weights represent the "Asian and other" category. Data for 2002 with 2000 census weights represent the "Asian only" category. Data for 2012 represent the "Asian only" category with 2000 census weights.

time and decrease, in general, relative to the size of the population.³

Race and ethnicity projections

To comply with the 1964 Civil Rights Act, the 1965 Voting Rights Act, and other domestic laws, Federal agencies, including the Census Bureau, are required to collect data on race and ethnicity. The number of racial categories has gone through numerous changes between the censuses. The categories established by the Office of Management and Budget prior to Census 2000 were "white," "black," and "Asian and other." American Indians/Alaska Natives and Hawaiian and Pacific Islanders constituted the "other" part of the "Asian and other" category.

The 2000 census allowed persons to choose more than one racial identity. Thus, the 2000 census uses the following racial categories: "white (only)," "black (only)," "Asian (only)," "American Indian or Alaska Native," and "Native Hawaiian and Pacific Islander." The term "only" refers to those who selected one race. Anyone who indicated that he or she was of more than one race was categorized as belonging to a multiple racial group. As a result of these changes, the 1990 and 2000 censuses are not directly comparable with regard to racial categories of population and the labor force. There are

no historical data for the new categories, causing breaks in the continuity of old categories. This situation has presented the Bureau of Labor Statistics with great challenges in the process of constructing labor force projections.

Problem of historical comparability. The Current Population Survey (CPS) is the source of historical data on the civilian noninstitutional population, labor force levels, and labor force participation rates used in BLS labor force projections.⁵ Although the CPS totals have been adjusted for the 2000 census, the actual transition to 2000-based racial categories began with the January 2003 release of CPS data.

The new racial categories are not exactly the same as those used in the past, but they are close enough to allow the development of time series of labor force participation rates as a basis for projecting these rates over the 2002–12 period. On the basis of projections of both the population and labor force participation rates of the new racial and ethnicity categories, labor force levels are projected for the various groups. However, the levels calculated under the new categories will not be the same as under the old ones. For example, the "white only," "black only," and "Asian only" groups in 2000-based actual and projected data are not directly comparable to the white, black, and "Asian and other" groups, respectively, in the historical data. In particular, the

² The "All other groups" category includes those reporting the racial categories of (1a) American Indian and Alaska Native or (1b) Native Hawaiian and Other Pacific Islanders and those reporting (2) two or more races. The category was not defined prior to 2003. Data for 2002 were calculated by BLS.

¹ Data for 1982 and 1992 represent the "Asian and other" category with 1990 census weights. Data for 2002 with 1990 census weights represent the "Asian and other" category. Data for 2002 with 2000 census weights represent the "Asian only" category. Data for 2012 represent the "Asian only" category with 2000 census weights.

sum of the three new one-race groups will not add to the total, because there is a residual comprising "all other racial groups," a category that includes American Indians, Alaska Natives, Native Hawaiians, and Pacific Islanders, as well as those reporting that they belong to multiple racial groups.

Trends in Population

Table 2 provides a snapshot of the U.S. population at 10-year intervals over the 1982–2012 period. The civilian noninstitutional population is expected to continue to grow at 1.1 percent

² The "All other groups" category includes those reporting the racial categories of (1a) American Indian and Alaska Native or (1b) Native Hawaiian and Other Pacific Islanders and those reporting (2) two or more races. The category was not defined prior to 2003. Data for 2002 were calculated by

annually during the 2002–12 projection period, reaching 241.6 million in 2012.

Beginning with the 20th century, several demographic events have had significant impacts on the size, composition, and growth of the population:

High rates of reproduction for the population born

prior to the 1920s, plus high immigration from Europe (chiefly from Italy, Ireland, and Poland) that occurred in the first two decades of the 20th century.

- The "birth dearth" of the late 1920s and early 1930s. The effect of the birth dearth is reflected in the declining number of persons aged 55 to 64 years from 1982 to 1992 and the drop in the number of those aged 65 to 74 years from 1992 to 2002. In 2002–12, the birth dearth is manifested in the slow growth of the 75-and-older age group.
- The "baby boom" starting in 1946 and lasting until 1964—a period of 18 years. The impact of this surge in the population level can be traced by following the movements of the baby-boom generation through age groups with the greatest increase in each period. For example, the 35- to 44-year age group increased most significantly (almost 12.2 million) over the 1982–92 period, and the 45- to 54-year age group had its greatest increase (nearly 11.8 million) over the 1992–2002 period. For the 2002–12 projection period, persons aged 55 to 64 years include the boomers and are expected to have the greatest growth in population, 11.5 million.
- The "baby bust," reflecting the drop in birthrates after 1965 and through the 1970s. The population in the age group following the baby boomers, including those aged 16 to 24 years in 1982–92, 25 to 34 years from 1992 to 2002, and 35 to 44 years in the 2002–12 projection period, show declining numbers. From 2002 to 2012, the number of persons aged 35 to 44 years is expected to decline by 3.8 million. This same age group increased by 12.2 million during 1982–92, when it contained a high concentration of baby boomers.
- The "baby-boom echo," reflecting a modest increase in births from the late 1970s through the early 1990s. The baby-boom echo is traceable to the increase in births of the women of the baby-boom generation and is reflected in the growth of the population aged 16 to 24 years during 2002–12.
- The massive migration to the United States that started in the 1970s and is continuing today. The dramatic increase in the immigrant population has resulted

in higher growth rates for the U.S. population. In addition, because all children born to immigrants in the United States are, by definition, natives, immigration has resulted in increased fertility rates for specific groups, again adding to the growth of the population.

The estimated future trends in the civilian noninstitutional population are based on the Census Bureau's middle population projection assumptions and reflect all of the foregoing demographic events. The Census Bureau provides the Bureau of Labor Statistics with an estimate of the future resident population. The Bureau of Labor Statistics then transforms the projections for the resident population to a projection of the civilian noninstitutional population by making several adjustments to the data. First, the Bureau estimates trends in the Armed Forces, to produce an estimate of the civilian population. Then, on the basis of another set of assumptions about the institutionalization of the different categories of population, the civilian population is transformed to the civilian noninstitutional population for the years covered by the BLS projections.

Table 2 shows the two estimates of the 2002 civilian noninstitutional population, one with the 1990 census weights and one with the 2000 census weights. In accordance with the 2000 weights, the civilian noninstitutional population was 217.6 million in 2002 and is projected to reach nearly 242 million, in 2012. The share of youths—persons aged 16 to 24 years—was 16.2 percent in 2002 and is projected to decrease to 15.7 percent in 2012. The working-age population (those aged 25 to 54 years) also will decrease in share, from 56 percent in 2002 to 52 percent in 2012. The older age segment of the civilian noninstitutional population, those aged 55 years and older, will increase its relative share, from 27.6 percent to more than 32 percent. The fastest-growing age category is the 55-to-64 age group, with 3.7 percent annual growth, followed by the 65-to-74 age group, with 2.4 percent growth.

As regards the sex categories, the civilian noninstitutional population of men stood at 104.6 million in 2002 and is projected to be 116.6 million in 2012, 48 percent of the total civilian noninstitutional population that year. The women's civilian noninstitutional population was around 113 million in 2002 and is projected to be nearly 125 million in 2012, 52 percent of the total civilian noninstitutional population that year. In 2012, the civilian noninstitutional population of women will thus be nearly 8 million more than men.

Census 2000 resulted in higher numbers than previous estimates for the total population and for some segments of the population. The group most affected was Hispanics, especially the younger age groups, which showed much higher population numbers. The Hispanic population was nearly 26 million in 2002 and is projected to increase to nearly 35 million in 2012, a growth rate of 2.9 percent, much faster than the

white non-Hispanic growth rate of 0.4 percent, over the 2002–12 period.

The youth population, aged 16 to 24 years, is expected to grow 0.7 percent annually. The population of the 55-and-older age group is projected to increase by 18 million over the projection period, or 2.7 percent per year. Those aged 55 to 64 are estimated to increase by 11.5 million over the period, or 3.7 percent annually, a rate higher than that of all other age groups. As a result of the birth dearth that followed the baby boom, the 35-to-44 age group will be the only group to decrease in numbers.

The impact of migration

Among the three major components of national population change—births, deaths, and international migration—the last is hardest to project, in large part because international migration is affected by many factors, some of which are difficult to predict. The Census Bureau uses age- and sex-specific rates from the 1980s to project net migration as a basis for its population projections. However, overall net migration still would account for a sizable proportion of the net population growth over the projected 2002–12 period.

Migration affects the demographic composition of the population in several ways. (See table 2.) The first is reflected in the rapid growth rate of some of the racial and ethnic categories, such as the Hispanic population. The projected growth rates for some of these racial groups are expected to be greater than they were the previous decade, increasing the groups' shares of the labor force.

The second way migration affects the composition of the population is by age distribution. For example, persons aged 25 to 34 years numbered 38.5 million in 1982. Ten years later, this same cohort was even larger, nearly 40 million. Similarly, the number of persons aged 20 to 24 years grew from almost 21 million to slightly more than 42 million 10 years later. Because everyone in these age groups has already been born, an increase in births does not affect the size of the groups. The only way these cohorts could increase their numbers is through net migration. Thus, the population at these relatively young age cohorts is significantly affected by migration.⁶ The increase in immigration levels since the mid-1980s was at least partially the result of the provisions of the Immigration Reform and Control Act of 1986. As the immigrants admitted into the country under the Act became citizens, they could sponsor the legal immigration of immediate relatives without being subject to numerical limits.

Labor force participation rates

The labor force participation rates—the proportion of the civilian noninstitutional population in the labor force—by age,

sex, race, and Hispanic origin are shown in table 3. The Census 2000 changes in the racial categories affected both population and labor force data in a comparable fashion. Therefore, it did not generally affect the observed trends in the labor force participation rates in any considerable way.

Participation rates by age. The youth labor force, consisting of persons aged 16 to 24 years, had a participation rate of 63.3 percent in 2002. The participation rate of this age group is expected to rise slightly, to 64.4 percent, in 2012. School attendance has been the main reason for the group's relatively low participation rate. Within the group, the participation rate for those aged 20 to 24 years is expected to rise from 76.4 percent to 78.2 percent.

The participation rate is highest among 25- to 54-year-olds; the group's rate has been higher than 80 percent for the last several decades. The participation rate of this group is projected to rise to 85.1 percent in 2012, from 83.3 percent in 2002.

Labor force participation rates generally decline dramatically for the 55-and-older age group relative to other age groups. The participation rate for these older persons historically had been declining until 1985. Since then, the 55-to-64 age group increased its participation rate from 55.1 percent in 1982 to 56.2 percent in 1992. The rate rose to 61.9 percent in 2002 and is expected to reach 65.1 percent by 2012. The 65-to-74 age group had a participation rate of 16.2 percent in 1982. The rate increased to 20.4 percent in 2000 and is projected to rise to 23.6 percent by 2012.

Participation rates by sex and age. The labor force participation rates of men always have been higher than those of women, both at the aggregate level and for the various age groups. As table 3 illustrates, the gap between the labor force participation rates of men and women has been shrinking for decades, reflected in the two groups' different trends in participation rates. In general, except for those 55 years and older, the rates for men have been declining. The overall labor force participation rate of men stood at 76.6 in 1982 and fell to 75.8 in 1992. In 2002, the participation rate of men declined further, to 74.1. The men's participation rate is expected to continue to decrease and reach 73.1 in 2012. In contrast, the rates for women have been increasing over these periods. The overall labor force participation rate of women was 52.6 percent in 1982, increasing to 57.8 percent in 1992 and 59.6 percent in 2002. The labor force participation rate of women is projected to be 61.6 percent in 2012. The labor force participation rate of women 55 years and older is expected to be 34.5 percent in 2012. Included in this age group are women 55 to 64 years, whose participation rate has the highest percentage-point change between 2002 and 2012. These women are projected to have a 60.6-percent participation rate in 2012.

The age-specific participation rates of men have been decreasing across many age groups; as a result, the aggregate

¹ Data for 1982 and 1992 represent the "Asian and other" category with 1990 census weights. Data for 2002 with 1990 census weights represent the "Asian and other" category. Data for 2002 with 2000 census weights represent the "Asian only" category. Data for 2012 represent the "Asian only" category with 2000 census weights.

Note: Because the transition to 2000-based racial categories began with the January 2003 cps data, the labor force participation rate of the "All other groups" category was not calculated.

labor force participation rates of men have consistently moved downward. The labor force participation rate for men 65 years and older began to increase in the 1980s. The labor force participation rate for men 65 to 74 years increased by 4.3 percentage points from 1992 to 2002, reversing a trend dating back to 1890. This group's labor force participation rate is projected to be 29.1 percent in 2012, up 3.6 percentage points from the 2002 figure.

The overall expansion of the U.S. economy over the past several decades, the provision of inflation-adjusted Social Security and Medicare benefits, and the growth of pensions and nonpension assets has provided more people with an adequate standard of living in retirement. All these factors may explain the declining labor force participation of men, particularly aged 65 years and older. However, since 1985, the decrease in the labor force participation rate has stabilized.

A number of reasons explain why the overall labor force participation rate of men had been decreasing up until the mid-1980s and why the labor force participation rate of men aged 55 years and older has started an upward trend.

First, during the 1950–80 period, defined benefit pension coverage became more widespread. Under this plan, workers realized a higher return on pension benefits by retiring as soon as they became eligible. During most of the 1980s, employment downsizing plans frequently included early pensions and lump-sum payments to older workers. By contrast, since the end of the 1980s, the conversion of pension plans from a defined benefit to a defined contribution approach has discouraged early retirements and reversed the declining trends of participation rates for men aged 55 years and older. The share of defined contribution plans increased from about 20 percent in 1981 to nearly 60 percent in 2000.

Research has shown that labor force participation rates drop significantly at ages 62 and 65, which are, respectively, the earliest age at which one can retire and receive Social Security benefits and the "normal" age at which one can retire and receive full Social Security benefits.⁸

Second, beginning with the year 2000, the normal retirement age for receiving Social Security benefits increased, and it will continue to do so gradually on a prescheduled basis.9 According to the new schedule, the size of the benefit is lowered for each month a recipient retires younger than the normal retirement age. The new provision will encourage workers to continue working later in life. Under this plan, starting in the year 2000, the age of retirement increased by 2 months for those born in 1938, 4 months for those born in 1939, 6 months for those born in 1940, and so on. All those who were born in 1937 or earlier are exempted from the law. People born between 1943 and 1954 (a large portion of the baby boomers) will be eligible for retirement when they reach 66. For people born in 1960 and later, the normal retirement age will be 67 years. The reduced benefits will encourage the large number in the labor force who are dependent on Social Security benefits for their entire income to work longer, or else they will end up with lower benefits during their retirement years.

The removal of the "earnings limit" law, better known as the Senior Citizens Freedom to Work Act, in 2000 has eliminated work disincentives for seniors. Prior to 2000, the earnings penalty, in the form of reduced benefits for those workers aged 65 to 70 years who earned wages, was a major disincentive to working and resulted in lower participation rates.

Participation rates by sex. Men aged 25 to 54 years are strongly attached to the labor force, and their labor force participation rates are mostly in the low- to mid-90-percent range. For most age groups of men under 55 years, the drop in participation was greater in the 1992–2002 period than in the 1982–92 period.

Unlike men's rates, the labor force participation rates of women have been increasing across all age groups over the past several decades. Women aged 45 to 54 years increased their participation by 11 percentage points during 1982–92, the highest among all age groups. The same cohort displayed the greatest increase in participation, 8.6 percent, in the 1992–2002 period, when they reached ages 55 to 64. However, for the 2002–12 period, when this cohort will be 65 to 74 years, they will yield their number-one ranking to a group of younger women: those aged 55 to 64 years, whose labor force participation rate will increase by 5.4 percent. Interestingly, men aged 65 to 74 years are expected to increase their participation more than women in that age range.

As table 3 indicates, the labor force participation rates of women and men have been converging. The gap in aggregate rates is expected to shrink by 12.5 percentage points over the 1982–2012 period, from more than 24 percentage points in 1982 to 11.5 points in 2012. In 1982, each group of women aged 25 to 54 years had labor force participation rates 28 percentage points lower than men the same age. By 2002, these differences had dropped by 15 percentage points; by 2012, they will be less than 11.5 percentage points. For workers aged 16 to 24 years, the difference in 2002 was relatively small and is expected to get even smaller. For older men and women, the difference in participation rates, measured by percentage points, was even smaller, reflecting a significantly lower participation at older ages.

Participation rate by race and Hispanic origin. Differences in labor force participation by race and Hispanic origin are usually not as great as those observed by age and sex.

| | Labo | or force participatio | n rate | Comp | osition of populatio | n by age |
|--------------|----------|------------------------|---|----------|------------------------|---|
| Age | Hispanic | White non- Hispanic | Difference (white non- Hispanic less Hispanic) | Hispanic | White non- Hispanic | Difference (white non- Hispanic less Hispanic) |
| 6 and 17 | 29.8 | 39.0 | 9.3 | 4.7 | 3.6 | -1.1 |
| 8 and 19 | 66.2 | 63.0 | -3.2 | 5.1 | 3.4 | -1.7 |
| 0 and 21 | 79.8 | 76.0 | -3.8 | 5.7 | 3.3 | -2.4 |
| 2 to 24 | 90.2 | 86.7 | -3.5 | 8.6 | 4.7 | -3.9 |
| 5 to 29 | 92.8 | 93.1 | .2 .3 | 13.3 | 7.6 | -5.8 |
| 0 to 34 | 94.1 | 94.3 | .3 | 14.9 | 8.4 | -6.4 |
| 5 to 39 | 92.5 | 93.8 | 1.3 | 10.5 | 9.7 | 8 |
| 0 to 44 | 91.7 | 93.0 | 1.3 | 11.3 | 10.4 | 8 |
| 5 to 49 | 87.6 | 91.5 | 3.9 | 6.9 | 10.4 | 3.5 |
| 60 to 54 | 84.4 | 88.2 | 3.7 | 6.1 | 9.2 | 3.1 |
| 55 to 59 | 75.9 | 79.4 | 3.5 | 3.9 | 7.6 | 3.8 |
| 0 and 61 | 65.5 | 68.5 | 3.0 | 1.3 | 2.5 | 1.2 |
| 2 to 64 | 48.9 | 51.2 | 2.2 | 1.7 | 3.3 | 1.6 |
| 55 to 69 | 29.8 | 32.7 | 2.8 | 1.9 | 4.8 | 2.9 |
| 70 to 74 | 16.4 | 18.0 | 1.6 | 1.6 | 4.2 | 2.6 |
| 75 and older | 7.1 | 7.8 | .7 | 2.7 | 6.9 | 4.2 |

However, changes in labor force rates over time differ among the various groups. When changes in participation rates are combined with different patterns of population growth, substantial differences in the future labor force result.

The following tabulation ranks the various racial and ethnic categories in terms of their labor force participation rates in 2002, with 1 indicating the highest rate and 4 the lowest:

| Total | Men | Women | Rank |
|------------|------------|------------|------|
| Hispanic | Hispanic | Black | 1 |
| White non- | | White non- | |
| Hispanic | Asian | Hispanic | 2 |
| | White non- | | |
| Asian | Hispanic | Asian | 3 |
| Black | Black | Hispanic | 4 |
| | | | |

Note that the rankings by race differ by sex. Hispanic men have the highest overall labor force participation rate. Hispanic women, by contrast, have the lowest participation in the workforce relative to other racial and ethnic categories. For blacks, the situation is reversed, with men having the lowest participation rate and women the highest.

The high labor force participation rate for Hispanic men reflects, in part, their age structure. Hispanics have a younger population, with a greater proportion at the ages of higher labor force participation. As table 4 shows, the labor force participation rates for Hispanic men are higher at ages 18 and 19, 20 and 21, and 22 to 24. The table also shows that Hispanic men have proportionally more young men than the white non-Hispanic population has. The aggregate labor force participation rate for a given racial or ethnic group can be expressed as the weighted sum of the age-specific rates, in which the weight for each age group is its share of the total population. If, on the one hand, Hispanic men had the age distribution of white non-Hispanic men in 2002, while retaining their own labor force participation rates, their aggregate labor force participation rate would have been 72.2 percent, significantly lower than their actual rate (80.2 percent) and only slightly lower than the rate for white non-Hispanic men (73.8 percent). (See table 4.) If, on the other hand, white non-Hispanic men had the population distribution of Hispanic men in 2002, their overall participation rate would have been 81.1 percent, higher than their actual rate and above the 80.2percent rate for Hispanic men. Thus, the aggregate labor force participation rate is a result of the age distribution of the population, as well as the labor force participation rates of the different age categories.

The preceding examples indicate that age, sex, and race are important in describing the variations in labor force participation rates. The ranking of the overall participation rates in 2012 is projected to change the rankings of the different racial and ethnic categories that year:

| Total | Men | Women | Rank |
|---------------------|---------------------|---------------------|------|
| Hispanic | Hispanic | Black | 1 |
| Asian | Asian White non- | Asian White non- | 2 |
| Black White non- | Hispanic | Hispanic | 3 |
| Hispanic | Black | Hispanic | 4 |

For the total labor force participation rates by racial groups, compared with 2002, Hispanics retained their place in the ranking and Asians achieved second place, followed by blacks and white non-Hispanics. The rankings for men did not change from 2002. Asians are projected to have the greatest increase, with a 2.4-percentage-point rise in their overall rate over the 2002–12 period. This increase reflects a 3.4-percentage-point gain in participation rate by Asian women. Overall labor force participation rates for blacks are expected to increase during the 2002–12 timeframe as well. The labor force participation of white non-Hispanics is expected to decrease slightly, reflecting decreasing trends for both women and men.

Projected labor force participation rates

The overall labor force participation rate is projected to rise by 0.6 percentage point between 2002 and 2012. Increases in the rate are expected to be greatest for the 55-to-64 and 65-to-74 age groups. The age range of peak labor force participation in both 2002 and 2012 is still 25 to 54 years, with a participation rate in the mid-80-percent range. Thus, the baby-boom generation's aging by itself will act to slow overall participation growth, because baby boomers will be older than the age of highest participation.

The labor force participation rate of men is projected to decrease by 1.0 percentage point, slightly less than the 1.9-point decline registered over the last decade. The overall men's rate is a summary of the changes in the age composition of the population and changes in labor force participation for each age, as well as of the increased racial and ethnic diversity of the male population. For men in the peak ages of labor force participation, 25 to 54 years, the rates show no growth. Older men are expected to continue to have increasing participation.

The increase in the women's labor force participation rate over the past two decades has displayed a pattern of slower growth in each successive period. The Bureau projects that this pattern will continue for the 2002–12 period. For most age groups, labor force participation growth is projected to be greater during that period than during the previous 10 years. With the aging of the population, however, the increase in the aggregate women's labor force participation rate is anticipated

to be the same as it was during the previous 10 years. Each of the major age groups—16 to 24 years, 25 to 54 years, and 65 years and older—is expected to maintain or modestly increase its participation rate. The participation rate of 20-to-24-year-old women continues to increase and is expected to reach 75.1 percent in 2012. It is projected that the labor force participation rates of women 25 to 34 years, 35 to 44 years, and, in particular, 45 to 54 years also will increase over the projection period.

See footnotes at end of table.

The 55-to-64 age group, consisting of members of the baby-boom generation, is projected to have the next-greatest increase of a 5.4-percentage-point change in its labor force participation rate.

Historical changes in the labor force size

This section examines changes in the size of the labor force

over two periods: 1982–92 and 1992–2002. Over the 1982–92 period, larger numbers of the younger baby-boom generation entering the labor force resulted in a high annual labor force growth rate of 1.5 percent. At 1.1 percent, annual labor force growth over the 1992–2002 period was much slower. The labor force grew by nearly 18 million between 1982 and 1992 and by 14.4 million between 1992 and 2002. (See table 5.) The men's labor force grew by 12 percent over the 1982–92 period and then by 8.7 percent between 1992 and 2002. Women increased their numbers in the labor force by 21.7 percent over the 1982–92 period. This growth rate was reduced to 14.3 percent over the 1992–2002 period.

Age. Labor force changes by age over the 1982–92 period were influenced by the baby boomers and the birth-dearth group born in the late 1920s and early 1930s. The labor force

¹ Data for 1982 and 1992 represent the "Asian and other" category with 1990 census weights. Data for 2002 with 1990 census weights represent the "Asian and other" category. Data for 2002 with 2000 census weights represent the "Asian only" category. Data for 2012 represent the "Asian only" category with 2000 census weights.

growth of the baby boomers during 1982–92 was affected by both population growth and the rapid increases in women's labor force participation rates.

Between 1982 and 1992, the 25-to-54 age group grew by more than 20.9 million. Those aged 25 to 34 increased by 4 million, those 35 to 44 by more than 11.5 million, and those 45 to 54 by more than 5 million. Over the 1992–2002 period, the age group with the greatest change was those 45 to 54 years, with 9.9 million workers.

The baby bust that followed the baby boom caused a drop in the labor force of those aged 16 to 24 during the 1982–92 period and also of those aged 25 to 34 in 1992–2002. It is projected that this segment of the labor force will again decrease (by 2.5 million) in the 2002–12 labor force.

Sex. Although population growth was similar for both sexes during the 1982–92 and 1992–2002 periods, men's labor force

participation rates declined while women's increased. As a result, the labor force growth of men was slower than that of women in both the 1982–92 and 1992–2002 periods, whether measured by numbers of persons or rates of change. The population and labor force of post-baby-boom cohorts aged 16 to 24 years decreased for both men and women in the 1982–92 period. The labor force of young women aged 16 to 24 years dropped more than that for young men (12.5 percent, compared with 11.9 percent).

In 1992, the baby-boom generation was in the 25-to-54-year-old age group. The labor force of men in this age group soared by 23.6 percent over the 1982 figure. Meanwhile, the labor force of women in the same age group expanded even more rapidly, by 37.8 percent. Overall, however, the labor force growth of baby boomers during 1992 to 2002 was markedly lower than in the 1982–92 period.

From 1982 to 1992, both the population and the labor force

² The "All other groups" category includes those reporting the racial categories of (1a) American Indian and Alaska Native or (1b) Native Hawaiian and Other Pacific Islanders and those reporting (2) two or more races. The category was not defined prior to 2003. Data for 2002 were calculated by BLS.

participation of men between the ages of 55 and 64 years decreased. Consequently, the labor force of men aged 55 to 64 dropped by 8.7 percent. During the same period, the population of women in the same age group dropped by 0.8 percent, but because their participation rates increased by 4.7 percent, their labor force population increased by 3.0 percent.

During 1992–2002, the men's population grew nearly as much as in the previous decade. Men's participation rates declined across all age groups, except those aged 55 and older; as a result, the labor force of men continued to shrink. Women continued to experience rising labor force participation for all age groups, and as a result, their labor force still exhibited considerable growth.

Race and Hispanic origin. White non-Hispanics were the largest group in the labor force in 1982 and 1992, accounting for 81 percent and 77 percent of the total, respectively. This group accounted for 71 percent of the total labor force in 2002. Hispanics increased their share from 8.9 percent in 1992 to 12.4 percent in 2002. Blacks' share of the labor force increased from 10.3 percent in 1982 to 11.1 percent in 2002. In 1982 and 1992, the category of "Asians and others" had the smallest share of the civilian noninstitutional population, but also had the fastest labor force growth rate. As noted before, in Census 2000, the Asians in "Asians and others" became a separate group named "Asian only." As a result, the new "All other" racial group now includes Native Americans, Alaska Natives, Hawaiian and Pacific Islanders, and those identifying themselves as having a multiple racial heritage. The category of "Asians and others" was the fastest-growing racial group in the past, and that of "Asian only" is expected to be in the future.

Projected changes in the labor force

During 2002–12, the various age, sex, racial, and ethnic groups will experience different rates of change in their populations, leading to significant changes in the composition of the labor force. The total labor force is projected to grow by 1.1 percent annually and reach 162.3 million in 2012.

Age. The youth labor force stood at 22.4 million in 2002 and is projected to grow by 2 million, to 24.4 million, by 2012. The increase is significantly more than that posted in the previous decade. For the labor force aged 25 to 54 years, the projected increase is 5.1 million, significantly less than the increase over the 1992–2002 period. The labor force size of those aged 25 to 34 dropped by 4.5 million over the 1992–2002 period, but is expected to increase by 3.2 million in the 2002–12 period. The 35-to-44-year age group, which increased by 3.0 million during the 1992–2002 period, is projected to drop by 2.5 million from 2002 to 2012, an effect of the baby bust following the baby-boom expansion. The 45-to-54-year age group, made up

of the younger members of the baby-boom generation, is expected to increase at a slower rate than earlier.

The labor force of workers 55 and older is anticipated to grow by more than 10.2 million by 2012, the fastest growth among all age groups. Within that group, the 55-to-64-year-olds are expected to add 8.3 million to the labor force.

Sex. The men's labor force is projected to grow by 1.0 percent annually during 2002–12, while that of women is expected to grow by 1.3 percent per year. Because of the differential growth rates, women's *share* of the labor force is projected to increase from 46.5 percent to 47.5 percent.

Race and Hispanic origin. Hispanics are projected to grow 2.9 percent annually over the 2002–12 period and total about 24 million, or 14.7 percent of the labor force, in 2012.

The new "Asian only" racial group is not directly comparable to the "Asian and other" group in terms of historical data. The category of "Asians only" is expected to be the fastest-growing segment of the labor force. As was noted earlier, the data for 1982 and 1992 represent the "Asian and other" racial category with 1990 census weights. The data for 2002 and 2012, by contrast, represent the "Asian only" racial category with 2000 census weights.

The black labor force is projected to have an annual growth rate of 1.8 percent from 2002 to 2012 and is expected to reach 19.8 million the latter year.

The white non-Hispanic group will grow at a meager 0.3 percent, but will still remain the most populous group in 2012. The group's labor force is anticipated to grow by 2.8 million between 2002 and 2012, while its share is expected to drop from 71.3 percent to 65.5 percent over the period.

Dynamics

From 2002 through 2012, the dynamics of labor force change emerge from three distinct groups: entrants—those who will be in the labor force in 2012, but who were not in it in 2002; leavers—those who will exit the labor force after 2002 and before 2012; and stayers—those who were in the labor force in 2002 and will remain through 2012. ¹⁰ To the extent that the demographic composition of labor force entrants between 2002 and 2012 is different from the composition of those now in the labor force, the 2012 labor force will be different from today's labor force. The labor force also will affected by the demographic composition of those leaving it. Thus, the labor force of 2012 may be regarded as consisting of the labor force of 2002, plus the entrants, less the leavers.

The Bureau of Labor Statistics projects that, between 2002 and 2012, 40.5 million workers will enter the labor force and 23 million will leave. (See table 6.) These figures compare with 33.5 million entrants and 19 million leavers over the 1992–2002

Table 6. Civilian labor force, 1992, 2002, and projected 2012, and entrants and leavers, 1992–2002 and projected 2002–12

¹ Data for 1982 and 1992 represent the "Asian and other" category with 1990 census weights. Data for 2002 with 1990 census weights represent the "Asian and other" category. Data for 2002 with 2000 census weights represent the "Asian only" category. Data for 2012 represent the "Asian only" category with 2000 census weights.

² The "All other groups" category includes those reporting the racial categories of (1a) American Indian and Alaska Native or (1b) Native Hawaiian and Other Pacific Islanders and those reporting (2) two or more races. The category was not defined prior to 2003. Data for 2002 were calculated by BLS.

period. Between 1992 and 2002, entrants were more likely to be men. Leavers also were more likely to be men, because the men's labor force was, and is, older than the women's. However, the difference in share exhibited for the 1992–2002 period is projected to narrow somewhat, resulting in an almost equal share of women and men entering the labor force.

According to the BLS projections, by 2012, 20.5 million men will have joined the 2002 men's labor force of 77.5 million, and 12.8 million men will have left the labor force, resulting in a labor force of 85 million men in 2012. Similarly, nearly 20 million women are expected to enter the labor force over the 2002–12 period, while 10 million women are projected to leave. The relatively smaller number of women leaving the labor force will raise their share from 46.5 percent in 2002 to 47.5 percent in 2012.

The largest share of the 2002 labor force—83 percent—was made up of whites. More than 76 percent of the population expected to enter the labor force between 2002 and 2012 are projected to be whites, smaller than their 78.3-percent share of entrants over the 1992–2002 period. These proportions also are smaller than whites' share of the workforce, reflecting the group's lower population growth. As a result of the 31 million whites entering the labor force and the 20.8 million leaving over the 2002–12 period, the share of whites in the labor force is projected to be 80 percent in 2012—a drop of 4.7 percentage points from 1992. In the 1992–2002 period, white men supplied the most entrants—41 percent. However, they also supplied most of those leaving—50 percent.

The white labor force is projected to have an annual growth rate of 0.8 percent, less than that of the overall labor force. The slower growth reflects little migration of this demographic group to the United States and lower birthrates in the past, compared with other population groups. This combination results in relatively fewer labor force entrants

and relatively more labor force leavers—a reflection of the aging white male labor force. White women are projected to increase their participation more than any other group, but this faster growth rate will not be enough to offset the slow growth of their labor force of only 0.9 percent per year.

Blacks are projected to make up 12.2 percent of the labor force, or a total of 19.8 million, in 2012. Blacks are expected to add 5.5 million entrants to the labor force between 2002 and 2012—13.7 percent of all new entrants during the period and less than the 14.3 percent that entered between 1992 and 2002. With the 2.3 million blacks projected to leave the labor force over the period, the group will increase in number, and by 2012, the black share of the labor force is expected to be 12.2 percent, up 1.1 percentage point from the 2002 figure. The black labor force is anticipated to grow faster than the overall labor force because of the higher-than-average population growth of blacks resulting primarily from higher-than-average birthrates.

In 2002, Hispanics represented 12.4 percent of the labor force, with nearly 18 million workers. Because of their higher levels of migration, nearly 8 million Hispanics are projected to enter the labor force during the 2002–12 period. Reflecting their relatively young age composition, only 2 million Hispanics are expected to leave the labor force, so the number of Hispanics in the labor force is projected to grow by more than 5.8 million. By 2012, the Hispanic labor force is anticipated to reach 23.8 million, 4 million more than the black labor force. The Hispanic share of the labor force is expected to grow both because of overall population growth—from higher birth levels and increased migration—and because of increases in the participation rate of Hispanic women.

In 2002, the Asian labor force totaled 6 million. About 1.8 million members of this group are expected to enter the labor force during the 2002–12 period, and a similar number are

projected to leave, so the group is expected to number nearly 9 million by 2012.

The aging labor force

Median age. Median age is one of the various ways by which the age of the labor force can be measured. The median age of the labor force was at a peak level in 1962 at 40.5 years. As the baby-boom generation entered the labor force, the median age of the labor force decreased steadily until 1980; since then, as the baby boomers have aged, so has the labor force. With both the population and the labor force aging, the median age of the labor force in 2012 is projected to exceed the level reached in 1962. (See table 7.) The following tabulation gives median ages for the civilian noninstitutional population and labor force aged 16 years and older:

| | 1992 | 2002 | 2012 |
|-------------|------|------|------|
| Population | 40.1 | 40.3 | 45.3 |
| Labor force | 36.6 | 40.0 | 41.4 |
| Difference | 3.5 | .3 | 3.9 |

The median age of both groups is increasing, but the median age of the population was increasing more than that of the labor force between 1992 and 2002. Over the 2002–12 period, the median age of the population is expected to rise by 5.0 years, while the median age of the labor force is projected to increase by 1.4 years. The median age of the labor force is less than that of the population because the labor force participation rates of

older persons are much lower than the rates of young workers. The growth of the older population, combined with the increase in the group's participation rates, resulted in the projected increase by 1.4 years in the median age of the 2012 labor force, exceeding the highest level ever recorded, in 1962.

Historically, white non-Hispanic labor force participants have been older than the rest of the labor force. This disparity is projected to continue and reach 1.8 years in 2012. Compared with whites, the black and Hispanic segments of the labor force both are younger and have higher fertility rates. As a result, young black and Hispanic workers—those between 16 and 24 years—are expected to increase the shares of their respective labor forces. Black participants in the labor force have been about 1.5 to 3.1 years younger than the overall labor force—a gap that is projected to continue through 2012. In 2002, the median age of Asian labor force participants was 1.6 years less than that of the overall labor force; the difference is expected to decrease to 0.5 year by 2012. Hispanic participants generally have been younger, due to their higher fertility rate. Hispanics are projected to continue having a lower median age than that of the overall labor force, but to age from a median of 34.2 years in 2002 to 36.6 years in 2012, reflecting the aging of earlier immigrants. The median ages of all racial and Hispanic groups are expected to increase during the 2002-12 period.

Age composition. Another way to measure the age of the labor force is by looking into its age structure. The labor force is getting older if the proportion of the 55-and-older or the 65-and-older

age group in it is increasing or if the share of those under 25 is decreasing. Table 8 presents such information for the population and labor force aged 16 and older, by sex and age groups.

From 1982 to 2002, the proportion of those 65 and older in the population increased. This proportion is expected to rise to 16.7 percent by 2012. The proportion of persons 16 to 24 years in the labor force decreased over the 1982–2002 period and is expected to decline further, to 15.7 percent by 2012. Accordingly, on the basis of both the median age and the age structure of the labor force, the population is getting older. Since 1992, the proportion of 25-to-39-year-olds has decreased, and it is expected to continue decreasing through 2012.

Looking at the composition of the population by sex, one sees that the same general patterns hold. However, the male population has proportionately more youths than the female population, reflecting men's higher proportion of births, slightly higher current migration, and higher mortality. Relatively more women are in the older ages.

Economic dependency. The economic dependency ratio is the number of persons in the total population (including the Armed Forces overseas and children) who are not in the labor force per 100 of those who are in the labor force. The following tabulation shows the economic dependency ratio by age for selected years from 1975 to 2002 and for 2012 (projected):

| Year | Total population | Under 16 years | 16 to 64 years | 65 years and older |
|------|------------------|-------------------|-------------------|-----------------------|
| 1975 | 126.3 | 61.4 | 44.2 | 20.7 |
| 1980 | 108.9 | 50.7 | 37.4 | 20.8 |
| 1985 | 103.3 | 47.3 | 34.2 | 21.8 |
| 1990 | 98.3 | 45.8 | 30.5 | 22.1 |
| 1995 | 96.6 | 48.6 | 25.7 | 22.3 |
| 2000 | 95.4 | 45.3 | 25.9 | 21.9 |
| 2002 | | 43.6 | 26.9 | 21.2 |
| 2012 | 85.0 | 38.9 | 25.9 | 20.1 |

For every 100 persons in the 2002 labor force, about 92 were not. Of the 92, 44 were children, 27 were 16 to 64 years of age, and 21 were 65 years and older.

In 1987, for the first time ever, more Americans were in the

labor force than were not. This trend is expected to continue throughout the entire projection period, with the estimated number of persons not working falling to 85 per 100 workers in 2012.

Over the last three decades, as the number of births diminished and the baby boomers moved to ages older than 16, the economic dependency ratio dropped. Most of the 34-percentage-point drop for the total population between 1975 and 2002 stemmed from the decline in the number of births. The portion of the ratio attributed to children is projected to continue dropping, despite somewhat higher fertility. The remainder of the historical drop is attributable to higher labor force participation among women aged 16 to 64 years. The ratio for this group dropped 17.3 points, from 44.2 in 1975 to 26.9 in 2002. The ratio is projected to continue decreasing and reach 25.9 in 2012.

The part of the dependency ratio that had been steadily increasing is the portion attributable to older persons (those 65 years and older). In 1975, this was by far the smallest part of the dependency ratio, and it is expected to still be the smallest proportion by 2012. However, between 1975 and 1990, the older persons' dependency ratio grew 1.4 percentage points. It fell again in 2002, to 21.2 per 100, representing the entry of the birth dearth of the 1930s into the 65-and-older group. The dependency of this group is expected to decline further, to 20.1 in 2012.

THE LABOR FORCE IN 2012 IS EXPECTED TO BE OLDER AND TO BECOME MORE DIVERSE. With the aging of the baby-boom generation, the workforce is projected to grow older. The median age of the labor force is expected to rise; the projected age of 41.4 for 2012 would exceed the highest level ever recorded. Hispanics are anticipated to become the largest minority group in the labor force, and women will likely continue to participate more. The dependency ratio is projected to continue to decline and is expected to reach 85 people not working per 100 people working. Between 2002 and 2012, nearly 122 million workers are expected to remain in the labor force, 40 million workers to enter, and 23 million—up 17.4 million from the 2000 level. The increase represents a continuation of the 1992–2002 growth rate.

Notes

¹ The civilian labor force consists of employed and unemployed persons actively seeking work, but does not include any Armed Forces personnel. Historical data for this series are from the Current Population Survey, conducted by the U.S. Census Bureau for the Bureau of Labor Statistics.

² Projections of labor force participation rates for 136 age, sex, race, and Hispanic-origin groups are developed by first estimating a trend rate of change, usually based on participation rate behavior during the previous 8-year period. Then the rate is modified whenever

the time-series projections for a given group appear inconsistent with the results of cross-sectional and cohort analyses. This second step ensures consistency in the projections across the various demographic groups. For further information, see *Handbook of Methods* (Bureau of Labor Statistics, 1999), Chapter 13, "Employment Projection"; on the Internet at http://stats.bls.gov/opub/hom/homch13_a.htm.

- ¹⁰ The numbers of entrants and leavers are computed by comparing the labor force numbers for a given birth cohort at two points in time. If the numbers at the second point are larger, the difference is termed the entrants; if the numbers at the second point are smaller, the difference is the leavers. These concepts understate the numbers likely to enter and leave the labor force over the period covered by the two points in time, but are still a valid comparison. As with measures of geographic mobility, which also do not measure all the changes over a period, we do not call the two groups *net* entrants and leavers. Flor a further discussion of the methods involved, see Howard N Fullerton, Jr., "Measuring Rates of Labor Force Dynamics," *Proceedings of the Social Statistics Section*, American Statistical Association, 1993.

Employment outlook: 2002-12

Industry output and employment projections to 2012

Employment in the dominant service-providing sector is expected to grow at a slower pace than in the 1992–2002 period, thereby slowing the projected growth in total employment

Jay M. Berman

he Bureau of Labor Statistics projects total employment in the United States to increase by 21.3 million during the 2002-12 period, rising from 144.0 million to 165.3 million. This increase results in a projected annual growth rate of 1.4 percent, which is slightly slower than the 1.6-percent rate of growth experienced during the preceding decade. The increase of nonfarm wage and salary jobs, from 131.1 million in 2002 to 152.7 million in 2012, is expected to account for most of the growth in total employment. The number of nonfarm self-employed workers and unpaid family workers is expected to increase by 144,000. Countering these gains, agricultural employment, which includes wage and salary workers, the self-employed, and unpaid family workers, is projected to decrease by 340,000 to settle at 1.9 million by 2012. (See table 1.)

Real industry output is projected to expand to \$23.3 trillion by 2012, an increase of \$6.4 trillion from the \$16.8 trillion level achieved in 2002. This translates into a projected 3.3-percent average annual growth rate and parallels the rate of growth exhibited during the past decade. Accounting for approximately 70.8 percent of the growth in total nominal output, the service-providing industries are projected to

reach \$15.5 trillion by 2012. Even though output in this sector is expected to grow by \$4.5 trillion by 2012, its projected 3.5 percent growth rate is slightly slower than that generated during the past decade. This is contrasted against the 3.0-percent annual growth expected by the goods-producing sector, which is faster than the historical 2.3 percent growth rate that this sector experienced between 1992 and 2002. Even with the relatively accelerated rate of output growth in the goods-producing sector, excluding agriculture, its share of current-dollar total output, however, will continue to decline from 31.4 percent in 1992 to 25.1 percent by 2012.2 Annual output growth in agriculture is expected to grow slightly from the previous 10-year period, to 1.6 percent annually. Its share of total output, however, will also decline, dropping from 2.2 percent in 1992 to 1.3 in 2002. (See table 2.)

The aggregate picture of the 2002–12 economy sets the projected labor force growth rate equivalent to that of the previous 10-year period, assumes a slower growth rate for GDP, and projects output to continue to outpace labor force growth due to productivity gains. Macroeconomic factors provide the foundation for the industry and output projections and include the labor force and demographic changes, Government defense

Jay M. Berman is an economist in the Division of Industry Employment Projections, Office of Occupational Statistics and Employment Projections, Bureau of Labor Statistics. E-mail: Berman_J@bls.gov.

¹ Employment data for wage and salary workers are from the BLS Current Employment Statistics (payroll) survey, which counts jobs, whereas self-employed, unpaid family workers, and agriculture, forestry, fishing, and hunting are from the Current Population Survey (household survey), which counts workers.

spending and tax policies, foreign economic activity, business investment decisions, personal consumption patterns, and aggregate productivity trends.³

Ten-year comparisons

BLS projects the labor force to grow at an annual rate of 1.1 percent between 2002 and 2012. This mirrors the 1.1-percent growth rate experienced over the 1992–2002 period. The growth rate of the nonfarm labor productivity index is projected to average 2.1 percent per year from 2002 to 2012, which is about the same rate that was observed over the previous 10 years. Annual GDP growth is expected to marginally retreat from its 3.2-percent rate over the 1992–2002 period to 3.0 percent over the projection period. Fixed nonresidential investment, with a projected 6.6-percent annual rate of growth, is expected to be the GDP component with the fastest growth

potential, followed by exports' 5.7 percent. Expected to still account for almost 70 percent of the economy's output, personal consumption expenditure is expected to grow at 2.8 percent over the projected period.

Trends by sector and industry. Virtually all of the projected employment growth in the economy will be posted by the service-providing sector, reflecting its large relative size. Making up 75.3 percent of total employment in 2002, this sector will continue to enhance its dominance by almost eclipsing the 130 million job mark by 2012 and increasing its share of total employment to 78.2 percent. The goods-providing sector is expected to add 262,000 more jobs over the projected period than it did over the past decade, for a total employment level of 23.3 million jobs in 2012. However, its relatively slow 0.3-percent projected annual rate of growth is dwarfed by the expected 1.8-percent pace and the 20.8 million jobs created by

² Includes agricutlure, forestry, fishing, and hunting data from the Current Population survey, except logging, which is from the Current Employment

Survey and government wage and salary workers, which are excluded.

³ Workers who hold a secondary wage and salary job in agricultural production, forestry, fishing, and private household industries.

⁴ Wage and salary workers who hold a secondary job as a self-employed or unpaid family worker.

the service-providing sector. Three out of four jobs in the U.S. economy are accounted for by the service-providing sector.⁴

Within the service-prodviding sector, education and health services and professional and business services represent the industry divisions with the strongest employment growth, both in terms of absolute and percentage changes. Education and health services is expected to grow at an average annual rate of 2.8 percent and professional and business services is projected to grow 2.7 percent—double the expected rate for the economy as a whole, adding 5.1 million and 4.9 million jobs respectively—both making up almost half of the total employment increases that are expected by 2012. State and local government will be responsible for the economy's next largest source of employment growth, increasing by 2.5 million jobs. This sector's employment will grow to 21.2 million workers in 2012, while Federal Government employment is expected to hold steady at its 2002 level of 2.8 million jobs.

The construction industry, the only major goods-producing sector expected to post positive employment growth, is projected to increase by 1.0 million jobs, reaching 7.8 million in 2012. Manufacturing employment is projected to show little change over the projection period, declining by a mere 0.1 per-

cent annually and slightly dipping below its 2002 level of 15.3 million. This is in contrast to the sharper average annual employment declines in manufacturing of almost 1.0 percent experienced during the previous, 1992–2002, decade when this sector lost 1.5 million jobs. This trend is tempered by the fact that 76 percent of this total decline, or 1.1 million jobs, occurred during the recent 2001 recession. Employment in the mining industries is projected to continue its 1992–2002 historical decline by shedding jobs at a 1.3-percent annual rate to settle at 451,000 by 2012.

The limited employment growth in the goods-producing sector is expected to take place despite strong growth in output. Through productivity gains, output for the goods-producing sector is projected to increase by 3.0 percent annually, which translates into \$1.6 trillion in additional output. Output generated by manufacturing industries, the dominant goods-producing sector, is projected to expand by \$1.5 trillion to \$5.4 trillion in 2012. This sector's projected 3.4 percent average annual rate of growth in output augments the relatively slower 1.7-percent projected growth rate for the construction industry and rivals the 3.5-percent output growth expected by the service-providing industries.

International comparisons. Mirroring the trends in agriculture production and productivity in the beginning of the last century, output in the goods-producing industries and specifically manufacturing continued to grow, while employment declined as productivity increased. As the following tabulation illustrates, this phenomena is shared by most industrialized countries:⁶

| | Average annual 1982–2 | |
|----------------|--------------------------|----------------------|
| Country | Manufacturing employment | Manufacturing output |
| United States | -0.7 | 3.0 |
| United Kingdom | -2.1 | 1.3 |
| Italy | 9 | 1.8 |
| Japan | 9 | 2.3 |

The United Kingdom and Italy, examples of the industrialized nations of Europe, and Japan also experienced continual productivity-led employment declines in their manufacturing sectors. However, spurred by capital investments, advances in technologies, and improvements in operational methods, production was able to increase, while fewer workers were required. On average, these four countries managed annual output increases of 2.1 percent between 1982 and 2002. However, increasing labor productivity allowed these countries to demand less labor—dropping by an average annual rate of 1.1 percent over the same 20-year period. Even though these countries share similar employment patterns with the United States, productivity levels in the United States have historically surpassed the rest of these countries—contributing to this country's historical higher rates of output growth.

The U.S. economy, however, is expected to remain service-dominated as that sector's output reaches \$15.5 trillion by 2012. The goods-producing sector, alternatively, is expected to generate \$6.4 trillion in output by 2012. Mirroring their employment influence, 37.8 percent of the projected nominal output for the service-providing industries will be attributed to financial activities and professional and business services. Highlighting this sector and setting the pace for the overall economy, information industries are projected to post the fastest output growth with a 5.3 annual rate, reaching \$1.5 trillion by 2012.

Service-providing sector

Information. The fastest growing sector in the economy, with a 5.3-percent projected output growth rate, is the information sector, which provides publishing, Internet, cable, and telecommunication services. Accounting for 39.8 percent of this sector's projected growth in output and 27.3 percent of its total employment, telecommunications, except cable and

other programming distribution is expected to grow by 4.9 percent annually to reach \$645 billion by 2012. Providing domestic and international telephone communications, including cellular services, this industry's main demand sources will be advanced technology and competition lowering prices for high-speed Internet access and wireless telephone services, as well as deregulation expanding the breadth of offered residential telecommunication services. In addition, business demand is expected to rise as companies increasingly rely on their telecommunication systems to conduct electronic commerce. This industry's employment gains, however, are expected to be limited by productivity gains, as technological improvements such as fiber optic lines and advanced switching equipment, increase the data transmission capacity of telecommunication networks. Employment for this industry is projected to stabilize at its 2002 level of 1.1 million jobs. (See table 3.)

The software publishing industry is expected to be the Nation's fastest growing employer by 2012, with a projected annual growth rate of 5.3 percent. (See table 4.) Even though this represents a slowdown relative to the past decade, the 173.7 million more jobs created by this industry during the projected period will be the result of firms continuing to invest heavily in software. Such investments boost productivity, increase efficiencies, and have become the backbone of a largely technology based economy. One of the fastest sources of output growth is expected to come from the software publishing industry—an 8.4-percent increase in output.

Also resonating the information sector's trend, the Internet services, data processing, and other information services industry, is expected to be the third fastest and one of the largest sources of output growth in the economy by 2012. (See table 5.) Mainly providing Internet publishing and broadcasting, general access, and search facilities, this industry's output is expected to reach \$232.6 billion by 2012, reflecting an increase of \$145.7 billion and a 10.3-percent annual rate from its 2002 level.

Professional and business services. Adding 4.9 million jobs at an average annual rate of 3.9 percent between 1992 and 2002, the professional and business services group was the economy's largest and fastest growing sector. Jobs in this industry cluster are projected to increase at a 2.7-percent annual rate, to 20.9 million in 2012 from 16.0 million in 2002. Despite the relative slowdown in the rate of employment growth, it is still expected to almost double the 1.4 percent posted by the economy as a whole, which will maintain its position as one of the economy's fastest and largest source of job creation. With accompanying above-average output gains of 4.1 percent, rising by \$891.1 billion to \$2.7 trillion in 2012, this industry group is also expected to be the largest source of output growth in the service-providing sector.

¹ Includes agricutture, forestry, fishing, and hunting data from the Current Population Survey, except logging, which is from the Current Employment Survey and government wage and salary workers, which are excluded.

Note: Dash indicates data not available. n.e.c. = not elsewhere classified.

Fueling 7.4 percent average annual increases between 1992 and 2002, the demand for employment services, the largest industry within the professional and business services group, heightened as companies sought new ways to reduce costs and become more responsive to changes in market demand. Even though this industry, which includes temporary staffing services, professional employer organizations, and employ-

ment placement agencies, is projected to grow significantly slower than in the past, its 4.4 percent growth rate still ranks among the top five industries with the fastest employment increases. The projected addition of 1.8 million workers by 2012 translates into 5.0 million total jobs, and positions this industry as the second largest source of jobs created by 2012. (See table 6.) The catalyst for this industry's positive relative

² Comparable estimate of output growth is not available.

³ Workers who hold a secondary wage and salary job in agricultural production, forestry, fishing, and private household industries.

⁴ Wage and salary workers who hold a secondary wage and salary job as a self-employed or unpaid family worker.

⁵ Wage and salary data are from the Current Employment Statistics survey, which counts jobs, whereas self-employed, unpaid family workers, and agriculture, forestry, fishing, and hunting are from the Current Population Survey which counts workers.

⁶ Output subcategories do not necessarily add to higher categories as a by product of chainweighting.

momentum will be increases in the demand for temporary staffing services, as flexible work arrangements and schedules continue to proliferate. In addition, professional employer organizations are expected to continue their historical growth as companies, facing increasingly complex employee-related laws and regulations look to control costs, reduce risks, and provide more integrated services by contracting out their personnel management, health benefits, workers' compensation and unemployment insurance, tax, and payroll responsibilities. Employment placement agencies, which provide preliminary employment screening tasks and executive recruitment services, are expected to be the slowest employment services sector. Employment increases for this industry are projected to be tempered by reduced labor needs from online employment placement agencies and various segments of competition, for example, job matching Internet sites operated by educational institutions and professional associations.

The projected growth rate for employment in computer systems design and related services is 4.5 percent-among the five fastest in the economy and more than three times faster than the economy's average. Setting a staggering precedent over the 1992-2002 period, this industry's employment grew at a 10.1-percent annual rate, compared with 1.8 percent for total nonfarm job growth. Employment in computer systems design and related services, providing expertise in the field of information technologies, grew from 445,000 jobs in 1992 to 1.2 million in 2002, and is projected to increase to 1.8 million by 2012. Reflecting the expansion of electronic commerce, a growing reliance on the Internet, faster and more efficient internal and external communication, and the implementation of new technologies and applications, the 635,000 projected growth in jobs also ranks this industry among the economy's largest growing.7

The importance of computer systems design and related services industry can also be realized by its output growth position. As table 5 shows, this industry is one of the fastest growing, with a projected output growth rate of 9.0 percent annually. This projected growth rate is slightly higher than the 8.8-percent average annual rate of increase posted during the 1992–2002 period.

Employment in management, scientific, and technical consulting services is expected to increase from 732,000 in 2002 to 1.1 million in 2012—an annual rate of 4.5 percent and among the five fastest in the economy. Attributed to continued economic development and growing business complexity, businesses will continue to need advice on planning and logistics, implementation of new technologies, and compliance with government tax, environmental, and employee benefits and workplace safety laws and regulations.

Health services. The gradual aging of the population, coupled with advances in medical technologies that increase

life expectancies, will place health services as a dominant source of projected employment growth. This sector, comprising mostly health practitioners offices, private hospitals, and nursing and residential care facilities, is expected to account for 1 out of every 6 new jobs created by 2012. The resulting 3.5 million additional workers will be spread throughout this large and diverse sector.

Of the 241.6 million people aged 16 and older, 32.4 percent or 78.2 million are projected to be 55 or older by 2012. Their projected 2.7 percent annual growth rate is more than double the average annual increases for the population as a whole. The reality of an aging population will result in employment in nursing care and residential mental health facilities, which include hospices, nursing and convalescent homes, to grow by 559,000 and reach 2.6 million in 2012. However, this trend will be eclipsed by potential Government budget constraints, a continued shift towards less expensive home health care and assisted living, and a healthier elderly population.8 Community care facilities for the elderly and residential care facilities (not elsewhere classified), which provide assisted living services, is expected to grow at an average annual rate of 4.5 percent—third fastest in the economy. Growth in these types of facilities reflects the desire of many elderly to maintain an independent lifestyle. Employment in this industry is expected to expand by 382,000 to reach above the 1.0 million mark by 2012.

Echoing the same rational of maintained independence and nursing home avoidance, health care for the elderly that is provided at their home is expected to be the main driver behind the aggressive growth in ambulatory health care services—almost 670,000 additional jobs added at a average annual rate of 3.9 percent from 2002 to 2012.

Employment growth in private hospitals, facing industry cost pressures and increased utilization of clinics and other alternative care sites, will be the slowest within the health services industry. However, due to this industry's relatively large size, private hospitals are projected to be the fourteenth largest source of employment growth in 2012 —adding 632,000 jobs and reaching a total employment level of 4.8 million. Spurred to reduce costs, hospitals are increasingly providing services on an outpatient or ambulatory basis, limiting unnecessary or low-priority services, and stressing preventative care.9 These trends, in turn, will provide the impetus for the aggressive growth that is expected for offices of health practitioners and the outpatient care center portion of the ambulatory health care services industry. Offices of health practitioners, providing medical, surgical, and dental services outside the traditional hospital setting are expected to grow at a 3.3-percent average annual rate—significantly faster than the economy as a whole. The 1.2 million new jobs expected to be generated by offices of health practitioners rank this industry among the largest sources of employment growth in the economy. Reflecting the growing demand for services provided by offices of health practitioners, rising expenditures will also rank this industry among the largest in terms of output growth—consumers are expected to demand \$468.9 billion by 2012, an increase of \$136.6 billion over its 2002 level.

Social assistance. Employment within the social assistance sector, surpassing the 2 million mark in 2002, grew at a staggering 5.1 percent from 1992 to 2002—almost triple the employment growth rate for the overall economy. Even though that rate is expected to slow to 3.8 percent over the projected period, this sector, which provides diverse services ranging from community food, housing, and emergency relief services to child daycare services, is expected to be responsible for generating almost a million more jobs. This sector is also expected to maintain its robust historical 4.1 percent output growth rate over the projected period.

Leading this sector in terms of employment size and growth, employment in the individual, family, community, and vocational rehabilitation services industry is projected to increase at a 3.9-percent annual rate, to 1.9 million jobs in 2012 from 1.3 million jobs in 2002. This reflects the continued expansion of services for the elderly and families in crisis, as well as an increased emphasis on earlier and better integration of the physically disabled and mentally ill into society.

As the increase in the population of women of childbearing age was accompanied by a slight increase in the proportion of such women in the labor force, demand for child daycare services, the other industry within this sector, grew at a staggering pace—5.1 percent annually from 1992 to 2002. Even though these demographic changes are expected to abate over the projected 2002–12 period, government increases in funding and promotion, welfare reform legislation that require more welfare recipients to work, and an increasing amount of employer-operated daycare centers will keep this industry among the fastest growing in terms of projected employment. Employment in child daycare services is expected to increase by 316,000 jobs to 1.1 million by 2012.

Leisure and hospitality. Employment in leisure and hospitality industries increased by 2.5 million over the 1992–2002 period, posting an above average 2.4-percent annual growth rate. The projected 2002–2012 employment increase of 2.1 million translates into 14.1 million total jobs, and represents a slower annual growth rate of 1.7 percent. Primarily including food services and drinking places, this sector will continue to play a prominent job creation role in the economy—approximately 10 percent of new jobs are expected to be stimulated by this diverse industry group. Real output for this sector is expected to be maintained at its historical 3.0 percent annual pace, reaching \$797.2 billion by 2012.

Jobs in food services and drinking places are projected to

increase by 1.3 million from the 2002 level of 8.4 million to arrive at the 2012 level of 9.8 million. On an annual average basis, the projected employment growth rate of 1.5 percent is slower than 2.4 percent rate and 1.8 million jobs posted during the 1992–2002 period. Demographic factors such as increases in population, personal incomes, leisure time, and dual-income families will still contribute to this industry being the fifth largest source of employment growth by 2012. Output for food services and drinking places is projected to keep close pace with its 1992–2002 historical growth rate of 2.7 percent.

The amusement, gambling, and recreation industry, which includes a diverse group of casinos, amusement parks, and fitness clubs, is expected to be one of the fastest and largest sources of employment growth by 2012. Reflecting increasing personal incomes, leisure time, and awareness of the health benefits of physical fitness, the strong gain in jobs for this industry is an expected 410,000, rising to 1.7 million from the 2002 level of 1.3 million. Output is projected to grow at a rapid 4.2-percent annual rate, making this a \$126.0 billion industry by 2012.

Wholesale and retail trade. Wholesale trade is projected to add 638,000 jobs to its 2002 level of 5.6 million, to reach 6.3 million by 2012. Due in part to its relative size, the wholesale trade industry ranks as one of the main sources of employment growth over the projected period. The annual employment growth rate of 1.1 percent is comparable to the industry's annual growth rate over the previous decade. Hedging the growth in employment, the wholesale trade industry is expected to continue its consolidation trends because of globalization, and cost pressures. In addition, productivity-enhancing technology such as e-commerce will further constrain the pace of employment growth. However, the expansion of customer services should increase demand for this industry's supply and distribution services. Real output for wholesale trade is expected to increase by 4.7 percent annually through 2012, expanding by almost \$600 billion to \$1.6 trillion. This gives this industry the distinction of being the second largest source of projected output growth and one of the economy's fastest.

The retail trade industry is the Nation's largest employer, with about 15.0 million jobs in 2002. Even though the projected employment annual growth rate of 1.3 percent represents a slowdown relative to the past decade, this industry, by adding 2.1 million new jobs and reaching 17.1 million by 2012, will continue to be the dominant source of employment. Real output for retail trade is expected to grow to \$1.4 trillion in 2012 from \$1.0 trillion in 2002, or at an average annual rate of 3.4 percent.

Government. Employment in the public sector is projected to increase by 2.5 million from its 2002 level of 21.5 million

through 2012. This reflects an annual growth rate of 1.1 percent, slower than the total nonfarm wage and salary increase of 1.5 percent. Federal Government employment is projected to maintain its 2002 level of 2.8 million, adding only 12,000 jobs by 2012. Job growth generated by increased homeland security needs is expected to be offset by other Federal agency

budgetary constraints, the growing use of private contractors, and the transfer of some functions to State and local government. The expected stabilizing outcome is a divergence from this sector's historical employment declines of 1.2 percent annually from 1992–2002.

State and local government employment is projected to

increase from the 1992 level of 18.7 million to 21.2 million jobs by 2012. The annual rate of growth is expected to slow from 1.8 percent posted between 1992 and 2002 to 1.3 percent through 2012. Driving this growth is the expected 1.7 million jobs from State and local government education, which accounts for more than half of all State and local government employment. Even though flat enrollments for preschool, elementary, and secondary classes are projected, proposed government reforms such as universal preschool, all-day kin-

dergarten, and reduced class size should buoy the employment demand for this segment of State and local government education. Rising enrollments in post-secondary education, spurred by children of the baby boomers reaching college age and a general demand for continued career and skills training, therefore, will be the main catalyst for this industry's overall employment growth.¹⁰

Output for State and local hospitals is expected to moderately grow at 1.5 percent annually as these hospitals continue

to provide services to trauma victims, the poor, and uninsured persons. Employment growth, however, will be limited—increasing by a meager 0.3 percent annually to 1.0 million jobs in 2012 from 995,000 in 2002. This will be due to productivity increases, the trend of some communities eliminating certain services, and more State government hospitals closing or being converted into community general hospitals, which are

usually private, not-for-profit institutions.11

The rest of State and local government employment will grow as a consequence of the events surrounding September 11, 2001; the assumption of some Federal Government responsibilities; and an increasing population demanding more services. Budgetary constraints, reductions in Federal aid, and resistance to tax increases from citizens will work to impede this growth.

Goods-producing sector

Agriculture. Being the industry with the largest projected declines in employment, farms are expected to repeat their historical trend by shedding an additional 324,000 jobs and settling at 1.6 million workers by 2012. The agriculture sector as a whole is projected to experience the largest declines in employment for any major sector, 340,000 at a 1.6-percent annual rate. Real output, however, is projected to expand annually by 1.6 percent to \$351.6 billion in 2012, up from \$299.6

billion in 2002. The persistent dichotomy between farm employment and production is due predominately to continued productivity growth, which is facilitated by industry consolidations and more efficient farm machinery. The negative trends in employment is expected to be moderated somewhat by the rising demand for organic farm produce, increases in the number of farmer-owned and -operated cooperatives, and targeted government assistance, which all bode relatively well for small- to medium-sized farms. Support activities for agriculture and forestry, which include such services as farm man-

agement, cultivation, and harvesting, is expected to be the only agriculture component posting employment gains. Employment, rising by a modest 0.7-percent rate between 2002 and 2012, is expected to reach 133,000 by 2012.

Jobs in the mining sector are projected to decline at a 1.3-percent annual rate and reach 451,000 in 2012. This represents a loss of 61,000 jobs and a continuation of its 1992-2002 historical declines. The persistent long-term employment reductions are due to technology driven productivity increases, industry consolidation, stringent environmental regulations, and international competition.12 Real output is also expected to be reduced at an annual rate of 0.6 percent, contracting to its 1992 level of \$155 billion. Setting the pace for this sector's employment declines, jobs in metal ore mining, which are subject to industry consolidations and labor saving technologies, are projected to decline at an average annual rate of 4.8 percent. However, because metals are used primarily as raw materials by other industries, the metal ore mining industry is influenced by the strength of the general economy and is expected to be the only production-based mining sector to experience increases in output.

This scenario is juxtaposed against the coal mining industry, which is expected to be one of the fastest declining industries, both in terms of employment and output. Employment is expected to contract by an average annual 3.5 percent, while output is projected to decline by 1.1 percent. Although coal mining is the cheapest, most abundant fossil fuel and accounts for half of this country's electricity production, employment and production in this industry will be most influenced by how electric utility companies respond to stricter environmental regulations. As the costs of compliance increases, through, for example, the installation of costly cleaning and monitoring equipment, the demand for coal is expected to shrink. Therefore, output is expected to contract slightly ahead of its 1992 level of \$22 billion from its 2002 level of \$26 billion.

Accounting for the majority of this sector's employment in 1992, the oil and gas extraction industry will reverse its relative prominence by declining from 182,000 jobs in 1992 to 88,000 by 2012. The 34,000 jobs lost at a 3.2-percent annual rate between 2002 and 2012 ranks this industry among the economy's fastest and largest source of employment declines. Fluctuations in global oil and gas prices, strict environment regulations, limited access to Federal lands, and foreign competition will have a negative impact on this industry's real output¹³—declining by an annual rate of 0.9 percent to \$80 billion by 2012.

Construction. The construction industry, which is projected to add more than a million jobs by 2012 at a 1.4-percent average rate of growth, is the goods-producing sector's only source of employment growth. Reaching an employment level

of 7.8 million in 2012, the construction industry is also among the economy's top-10 largest source of employment growth. Real output, however, is projected to increase at a tamer annual rate of 1.7-percent—slower than the 2.8-percent annual rate achieved during the previous decade and almost half the projected rate for the economy as a whole.

Delayed replacement or remodeling of industrial plants and greater demand for aging-population related nursing, extended care, and high-technology medical treatment facilities will propel nonresidential construction to lead this aggregate segment. However, technology enhancements will dampen demand for new commercial construction, as nontraditional work and retail environments such as teleconferencing, telecommuting, and electronic shopping continue to proliferate. Total nonresidential investment in structures is therefore expected to grow by 1.8 percent over the 2002–12 period.

Residential construction, closely tied to demographic factors will grow at a 2.1-percent pace throughout the 2002–12 period. As baby-boomers reach their peak earning years, the demand for upgraded homes, second homes, and assisted living housing will increase. In addition, as their children, the echo boomers, augment the younger age groups, and the number of immigrants increases, the demand for single-family housing and rental apartments also is projected to increase.

Manufacturing. This sector's share of total employment is expected to continue to decline, while its share of total output is projected to be maintained—reversing its trend in the prior decade. Reflecting an average annual employment decline of 0.9 percent and an absolute job loss of 1.5 million from 1992 to 2002, manufacturing employment represented only 10.6 percent of total employment in 2002, down from almost 14 percent in 1992. During this decade, manufacturing employment peaked in 1998 at 17.5 million, up from 16.8 million in 1992. The projected, productivity-led declines in this sector's employment, even though relatively moderate at 158,000, will slightly lower its share of total employment to 9.2 percent in 2012. This translates into 15.2 million wage and salary manufacturing jobs maintained in 2012. Even though the 15.3 million jobs counted in 2002 represents the trough of the 2001 recession, the 2.3 million jobs lost since 1998 are not expected to be recovered.

Up against the dramatic historical output gains in the service-providing sector, the 2.3-percent average annual increases and the \$773.4 billion worth of additional real output that was generated by the manufacturing sector between 1992 and 2002 was not enough for this sector to maintain its 25.9 percent nominal output share in 1992—dropping to 21.1 percent by 2002. However, due to somewhat moderate output growth expectations in the service-sector and an accelerated manufacturing output growth prospect over the projected period, manufacturing's 2002 share of total nominal output is projected to be maintained. Consistent with overall economic

growth, real output for manufacturing is expected to increase at an average annual rate of 3.4 percent between 2002 and 2012—faster than the 1992–2002 historical 2.3 percent rate, and rivals the service-producing sector's projected 3.5 percent annual growth rate. Led by productivity gains and strong demand by consumers, businesses, and exports, manufacturing output is expected to increase by \$1.5 trillion to reach \$5.4 trillion by 2012.

The industry manufacturing groups that will lead the pace of output growth are: computer and electronic products manufacturing (11.8 percent); plastics and rubber products manufacturing (4.1 percent); machinery manufacturing (4.0 percent); and fabricated metal products manufacturing (3.4 percent). The industry groups that will contribute the strongest drags on employment are: apparel manufacturing (-11.0 percent); textile mills (6.1 percent); and leather and allied product manufacturing (4.0 percent). These industries are also projected to be the only manufacturing sources with declining output.

The computer and electronic products manufacturing group, which includes computer, communications, semiconductor, and navigational production, highlights the dichotomist relationship between the growth of manufacturing output and the productivity led declines in employment. For example, with a 24.2-percent projected growth rate, the computer and peripheral equipment manufacturing industry has the fastest growing real output of any detailed industry for which BLS prepares projections. Reaching \$2.3 trillion by 2012, a \$2.0 trillion increase over its 2002 output level, this industry is also the economy's largest source of projected output growth. (See table 7.) However, due to the introduction of new technology and automated manufacturing processes, this industry's employment is expected to exceed its 2.7 percent historical rate of decline, and lose 68,000 jobs over its 2002 level of 250,000.14

Communication equipment, with a projected output level of \$268 billion, is this group's second largest industry. Growing demand for wireless phones as quality and services improve, along with enhanced wireless computer applications and evolving forms of Internet connectivity will expand the output for the communications equipment industry annually by 10.4 percent, the economy's second fastest rate.

Real output for the plastics and rubber manufacturing group is projected to increase by \$8.2 billion to reach \$244.6 billion in 2012. Employment is expected to reach 991,000 by 2012—a 138,000 increase from the 2002 level. The resulting 1.5-percent average annual rate of growth in employment makes plastics and rubber manufacturing the fastest and largest growing group within the manufacture sector. Plastics product manufacturing, the dominant industry within this group, primarily molds plastics for manufacturing industries. Many of the most rapidly growing industries in the economy, including construction and industries manufacturing elec-

tronics, computers, communication equipment, and motor vehicles, use plastic products as an intermediate input in production. Demand by these industries will sustain employment and output growth in the plastics products industry throughout the projected period.

The industries within the apparel and textile mill groups are all among the most rapidly declining industries in terms of employment over the 2002-12 period. Because of its laborintensive nature, import competition and changing trade regulations are the most important factors behind the apparel industry's projected employment declines of 246,000, to 112,000 in 2012—greater than any other industry's reduction except agriculture. Transforming textile mill fabrics into clothing and accessories, this industry's output is also projected to decline by 7.6 percent annually, which is the economy's most aggressive pace. Real output is expected to contract from \$50.0 billion in 2002 to \$22.8 billion in 2012 as new automation, fierce retailer cost-cutting pressures, and consolidations all negatively influence this industry. Echoing the decline of the domestic apparel industry, the textile mills group will experience similar downward trends in employment and output. Employment, projected to contract almost by half, is expected to decline by 136,000 to 157,000 in 2012, while real output declines by 2.2 percent annually, to \$35.8 billion in

In 1992 and 2002, the largest share of nominal manufacturing output, more than 15 percent, was produced by the transportation equipment manufacturing group. By 2012, even though the percent share comanded by the computer electronic production manufacturing industry will run a close second, transportation equipment manufacturing will maintain its relative dominance. Highlighting this fact, transportation equipment manufacturing, which includes motor vehicle, aerospace, railroad, and shipbuilding is the largest manufacturer employer, with about 1.8 million workers in 2002. Amid a relatively small drop in employment over the projected period, this industry group will continue to be manufacturing's dominant source of employment. Jobs in aerospace product and parts manufacturing, the principal employment sector within transportation equipment manufacturing, is projected to decline by 83,000 workers to 386,000 by 2012. Real output for the aerospace product and parts industry, which produces aircraft, guided missiles, and space vehicles, declined from \$138 billion in 1992 to \$116 billion in 2002. The continued attention given to the Nation's security will increase the demand for military aircraft and equipment. However, output is expected to maintain its 2002 level as import competition intensifies.

Motor vehicle manufacturing production, the principal sector within transportation equipment manufacturing, in terms of output, stood at \$236 billion in 2002. Facilitated by healthy productivity gains, output is expected to increase by 3.1 percent annually to \$319 billion by 2012. This, however, represents a marginal

slowdown from the 3.6-percent growth experienced over the last decade. Output growth will be limited due to the anticipated slowdown in the growth of the driving age population, competition from foreign producers, improvements in vehicle quality that extend longevity, and safety and environmental regulations that increase production costs. Motor vehicle manufacturing employment in 2002 was 267,000—approximately the same level as that in 1992, and is expected to decline slightly by 0.6 percent annually from 2002 to 2012. The resulting decline to 251,000 jobs by 2012 will be a consequence of companies continuing to absorb productivity-enhancing technologies such as robotics, computers, and factory automation.

THE BLS PROJECTION for the goods-producing sector speaks for the economy as a whole: strong productivity led output gains, coupled with relatively marginal employment increases. Even though the service-providing industries will remain the economy's most dominant sector, the pace of output growth will be on par with its goods-providing counterpart. This represents a significant divergence from the service-providing sector's historical stronger rate of growth. Business fixed investment, the GDP component with the fastest growth rate, is expected to be the main catalyst behind this caveat. Even though demand from personal consumption will remain the

dominant source of output and employment generated in 2012, purchases of new construction and equipment by businesses will be responsible for the accelerated pace of the goodsproducing sector's projected output.

Furthermore, as the service-providing sector's pace of employment growth is expected to slightly decelerate, the goods-producing sector will witness a marginal expansion. This is a result of the manufacturing sector stabilizing its previously persistent employment declines and the positive job growth posted by the construction industry. Machinery, fabricated metal, and transportation equipment manufacturing are all large sectors that highlight this expected manufacturing phenomenon. Reflecting an ever-evolving economy, the desire by businesses to enhance productivity, and an aging population, the service-providing sector's most influential industries are professional and business services, and education and health services.

Mirroring trends in many industrialized countries, the latest round of BLS projections sets productivity gains as the medium through which output outpaces the projected growth in the labor force. In addition, its main themes are expected to be an economy that is dominated by the service-providing sector in terms of employment and output share, but witnesses significant gains in the goods-producing sector's rate of growth.

Notes

- ¹ This article uses the gross duplicated output concept. Gross duplicated output measures not only GDP, or all final demand purchases of new goods and services, but also all new goods and services produced as intermediate goods for use in further production. Real output is measured as a 1996 based chain-weighted Fisher index and is used for historical rate of growth comparisons. Real output on an industry basis does not add to their higher level aggregates because of chain weighting. See Charles Steindel, "Chain-weighting: The New Approach to Measuring GDP," Current Issues in Economics and Finance, Federal Reserve Board of New York, December 1995.
- ² Providing a more accurate measure of the relative importance of aggregated sectors of the economy, current-dollar output estimates were used in lieu of chain-weighted measures. See J. Steven Landefeld, Brent R. Moulton, and Cindy M. Vojtech, "Chained-Dollar Indexes: Issues, Tips on Their Use, and Upcoming Changes," Survey of Current Business, US Department of Commerce, November 2003, pp. 8–16.

Employment outlook: 2002-12

Occupational employment projections to 2012

Employment in professional and related and in service occupations are expected to increase the fastest and add the most jobs from 2002 to 2012, while office and administrative support occupations should grow about half as fast as the total; production occupations should grow very slowly

Daniel E. Hecker

otal employment is projected to increase by 21.3 million jobs over the 2002–12 period, rising to 165.3 million, according to the latest projections of the Bureau of Labor Statistics. This increase represents about 600,000 more jobs than were added over the previous 10-year period (1992–2002). The projected 14.8-percent increase, however, is less than the 16.8-percent increase of the previous 10-year period. Self employment is projected to decline 2.3 percent, from 11.5 to 11.2 million.

This article discusses a number of aspects of the projections along with related information:

- changes in the structure of employment at the major occupational group level;
- the detailed occupations² that are projected to grow fastest as well as those with the largest numerical increases and decreases, along with their current educational and training requirements and earnings; and
- the total job openings projected to occur due to growth in the economy and the net replacement needs resulting from workers who leave the labor force or transfer to other occupations

In this article, projected employment is analyzed from two perspectives—percent change and numerical change—because one can be large and

the other small, depending on the size of employment in the base year. The following example using data for two occupations generally requiring the same level of education—a bachelor's degree—illustrates the importance of viewing job outlook from both perspectives:

Employment of environmental engineers is projected to grow twice as fast as employment of accountants and auditors over the 2002–12 period, 38.2 percent, compared with 19.5 percent. However, the accountants and auditors occupation is projected to add more than 11 times the number of new jobs (205,000 compared with 18,000), because employment was so much larger than for environmental engineers in 2002 (1,055,000 compared with 47,000).

Major occupational groups

Among the major occupational groups, employment in the two largest in 2002—professional and related occupations and service occupations—will increase the fastest and add the most jobs from 2002 to 2012. (See table 1.) These major groups, which are on opposite ends of the educational attainment and earnings spectrum, are expected to provide more than half of the total job growth from 2002 to 2012. Employment is projected to grow about as fast as overall employment in management, business, and finan-

| 9-0000 Installation, maintenance, and repair occupations | 5,696 | 6,472 | 4.0 | 3.9 | 776 | 13.6 |
| 51-0000 Production occupations | 11,258 | 11,612 | 7.8 | 7.0 | 354 | 3.1 |
| 53-0000 Transportation and material moving occupations | 9,828 | 11,111 | 6.8 | 6.7 | 1,282 | 13.0 |

NOTE: Detail may not equal total or 100 percent due to rounding.

cial occupations and in construction and extraction occupations. Employment in installation, maintenance, and repair; transportation and material moving; and sales and related occupations will grow somewhat more slowly. The three slowest growing groups—all with rates less than 7 percent—are office and administrative support occupations; farming, fishing, and forestry occupations; and production occupations.

As a result of the different growth rates among the major occupational groups, the occupational distribution of total employment will change somewhat by the year 2012, but the relative ranking of the groups by employment size is not expected to change. Professional and related occupations will continue to rank first, while farming, fishing, and forestry occupations will continue to rank last. Professional and related and service occupations will significantly increase their relative share of employment—by 1.5 and 0.9 percentage points, respectively. However, office and administrative support occupations and production occupations should decrease significantly—by 1.2 and 0.8 points, respectively. (See table 1.)

The growth of occupational groups (and occupations) is determined, in large part, by growth in industries in which they are concentrated. For example, professional occupations are projected to grow the fastest, in large part because they are concentrated in some fast-growing industries such as healthcare and social assistance; and professional, scientific, and technical services; while production occupations are projected to grow very slowly, largely because 7 out of 10 are in the declining manufacturing sector.³

The number of *management*, *business*, *and financial* workers is projected to grow by 2.4 million from 2002 to 2012. Within this occupational group, about one-fifth of the new jobs will be in professional, scientific, and technical services,

which include management, scientific, and technical consulting, and accounting, tax preparation, bookkeeping, and payroll services. About 1 new job in 8 is projected for finance and insurance, and 1 in 9, for healthcare and social assistance. The self-employed in this group, accounting for one-fifth of the total, are projected to decline 5.6 percent. Overall projected growth among management, business, and financial workers is affected by the decline of farmers and ranchers, most self-employed, by 238,000. (See table 2.) Excluding farmers and ranchers, this major group is projected to increase 18.3 percent. The self-employed, excluding self-employed farmers and ranchers, are projected to increase 4.0 percent, with the largest increase for management analysts.

Employment in *professional and related occupations* is projected to grow the fastest and to add more workers (6.5 million) than any other major group. Three-tenths of the growth in these occupations is projected to take place in healthcare and social services, a quarter in government, and a seventh in professional, scientific, and technical services. There are eight occupational subgroups within professional and related occupations. Three occupational subgroups—education, training, and library; healthcare practitioners and technical; and computer and mathematical should account for three-quarters of the job growth.

A 6.1-percent increase is projected for self-employed professional and related occupations. Most growth among self-employed is projected for two subgroups—arts, design, entertainment, sports, and media occupations and computer and mathematical occupations.

Education, training, and library occupations are projected to grow faster than the average for all occupations, adding 2.1 million jobs as shown on p. 97 (also, see table 2):

¹ Total job openings represent the sum of employment increases and net replacements. If employment change is negative, job openings due to growth are zero and total job openings equal net replacements.

² This occupation was created by the OES survey. There is no SOC equivalent.

minor occupation group.

⁵ This occupation contains two or more detailed SOC occupations.

NOTE: Detail may not equal total or 100 percent due to rounding.

| Professional and related | Percent | Numeric chang |
|--|---------|----------------|
| occupations subgroup | change | (in thousands) |
| Computer and mathematical | 34.8 | 1,051 |
| Community and social service | 26.2 | 574 |
| Healthcare practitioners | | |
| and technical | 26.0 | 1,708 |
| Education, training, and library | 24.7 | 2,109 |
| Life, physical, and social science Arts, design, entertainment, | 17.2 | 212 |
| sports, and media | 16.5 | 393 |
| Legal | 16.2 | 190 |
| Architecture and engineering | 8.6 | 222 |

This group is projected to grow as the school-age population increases; a greater proportion of preschool-age children attend school; a greater proportion of students are provided with special education; and classes become smaller. In addition, rapid growth is expected in the number of adults attending both career and job training schools and selfenrichment classes. More than 3 out of 5 new jobs are projected for government and 1 in 5 for rapidly-growing private educational services.4

Healthcare practitioners and technical occupations are projected to add 1.7 million jobs, as the demand for healthcare

³ This minor occupation group contains a detailed occupation from another

⁴ Information about the detailed residual occupation for this broad occupation is not included.

services continues to grow rapidly. (See p. 101 for a discussion of reasons for growth.) More than 3 out of 4 new jobs in these occupations are expected to be in the healthcare industry. Relatively few new jobs, and slow growth, are projected in government.⁵ Registered nurses, by far the largest occupation in this group, should account for more than 1 out of 3 new jobs. The number of self-employed workers in this group is projected to decline slightly. Self-employed physicians are expected to decline significantly, as employment shifts into incorporated group practices, while self-employed registered nurses, chiropractors, veterinarians, and speech-language pathologists are projected to increase.

Computer and mathematical occupations are projected to add 1.1 million jobs, and grow the fastest among the eight subgroups. The demand for computer-related occupations should increase, despite the recent downturn, as a result of rapid advances in computer technology and the demand for new computer applications, including those for the Internet and Intranets. Growth will not be as rapid as during the previous decade, however, as the software industry begins to mature and as routine work is increasingly outsourced overseas. More than a third of new jobs will be in computer systems design and related services, and one-fifth will be in the information industry—primarily in software publishers, data processing and related, and Internet-related industries. In both groups, projected growth for these occupations exceeds 50 percent. In addition, in many industries, employment of these workers is projected to grow faster than the average for all occupations. Self-employed computer and mathematical workers are expected to increase 39.8 percent.

Community and social services occupations are projected to add 574,000 jobs. Continued rapid growth should result as the elderly population increases rapidly and as greater efforts are made to provide services for the disabled, the sick, substance abusers, and individuals and families in crisis. Within this occupational group, about 3 out of 5 new jobs are expected to be in the healthcare and social assistance industry and 1 out of 5 in religious organizations. Slow growth and 1 new job in 8 are projected for the large government sector.

Arts, design, entertainment, sports, and media occupations are projected to add 393,000 jobs. About one-fifth of these new jobs is projected for professional, scientific, and technical services, which includes both advertising and computer systems design and related services. One job in seven is projected for the information sector, which includes both motion pictures and publishing industries. About one-sixth of the growth is expected for self-employed workers (a 9.3-percent increase), with largest increases for writers and authors, graphic designers, musicians and singers, and photographers.

Architecture and engineering jobs are projected to grow slowly, adding 222,000 jobs. About 2 out of 5 new jobs in

these occupations are projected for the professional, scientific, and technical services industry. One new job in 6 is projected for the rapidly growing employment services industry, which provides employees to other industries on a contract or fee basis. One new job in 8 is projected for government. In manufacturing industries—which employed a third of these workers in 2002—little change is projected. Engineers, the largest occupational subgroup, is expected to grow 7.3 percent.

Life, physical, and social scientists are projected to add 212,000 jobs. More than a quarter of these jobs are projected for the professional, scientific, and technical services industry which includes scientific consulting services and scientific research and development services. Nearly a quarter of new jobs is projected in government and 1 new job in 7 is projected for rapidly-growing healthcare and social assistance. Self-employed are projected to grow slowly, with most growth among psychologists.

Legal occupations are projected to add 190,000 jobs, with about 7 of 10 projected for the legal services industry, where these occupations should increase rapidly. A quarter of all growth is projected for government. Paralegals and legal assistants are projected to grow the fastest, while lawyers should add the most jobs, 118,000. The number of self-employed workers in this group is projected to decline 7.0 percent, all among lawyers, reflecting the difficulty in establishing new legal practices.

Employment in *service occupations* is projected to increase by 5.3 million, the second largest numerical gain and second highest rate of growth among the major occupational groups. For these occupations, about 3 out of 10 new jobs, and fastest growth, are projected for the healthcare and social assistance industry. A quarter of new jobs are projected for the accommodation and food services industry. The number of self-employed service workers is projected to increase slightly.

Of the five subgroups making up service occupations, food preparation and serving-related occupations was the largest in 2002—with 10.2 million jobs—and is projected to add the most jobs, about 1.6 million. Nevertheless, it has the slowest projected growth. (See table 2.) Nearly 4 of 5 new jobs are projected for the accommodation and food services industry. The following tabulation shows the percent and numeric change for the services occupation subgroups:

| | Percent change | Numeric change (in thousands) |
|---|----------------|----------------------------------|
| Healthcare support | 34.5 | 1,143 |
| Protective service | 24.7 | 769 |
| Personal care and service Building and grounds | 20.6 | 917 |
| cleaning and maintenance Food preparation | 16.4 | 901 |
| and serving related | 15.8 | 1,607 |

Healthcare support occupations are projected to add 1.1 million jobs, growing the fastest of the services subgroups. (See p. 101 for a discussion of reasons for growth.) Seven out of eight new jobs are projected for the healthcare and social assistance industry. Self-employed healthcare support occupations are projected to grow 16.6 percent, with most growth among massage therapists.

Personal care and service occupations are projected to add 917,000 jobs. Nearly half of new jobs, and the fastest growth (51.6 percent) for these occupations, are projected in the healthcare and social assistance industry. One new job in 6 is projected for arts, entertainment, and recreation, which includes amusement parks and fitness and recreational sports centers. Overall growth is retarded by a 1.6-percent decline among the self-employed, who made up a quarter of all workers in this group in 2002. Declines among self-employed are primarily among first-line supervisors/managers of personal care and service workers (mostly proprietors of small businesses) and childcare workers.

Building and grounds cleaning and maintenance occupations are projected to add 901,000 jobs. Forty-five percent of new jobs, and fast growth, are projected for administrative and support and waste management and remediation services, which includes both services to buildings and dwellings and employment services. About 1 job in 8 is projected for healthcare and social assistance and 1 in 10 each in accommodation and food service and government. A 39,000 decline is projected in the private household sector, where 10 percent of these workers were employed. Only 2.9-percent growth is projected for the self-employed. Among the self-employed, landscaping and groundskeeping workers, as well as first-line supervisors/managers of these workers, are projected to increase, while maids and housekeeping cleaners are expected to decline.

Protective service occupations are projected to add 769,000 jobs. Half of the growth is projected for government, and nearly two-fifths is projected for rapidly growing investigation and security services.

Employment in sales and related occupations is projected to increase by 2 million. More than 3 out of 5 new jobs are projected for retail trade, and 1 in 8 for wholesale trade. The self-employed made up 12 percent of this group in 2002. Their employment is projected to decline by 9 percent, with the largest decreases among self-employed first-line supervisors/managers of sales workers (owners of stores or other marketing businesses); retail sales workers; and door-to-door sales workers, news and street vendors, and related workers.

Employment in *office and administrative support occupa*tions is projected to increase by 1.6 million but grow slowly. More than a quarter of these new jobs are projected for rapidly-growing employment services, which provides employees to other industries on a contract or fee basis. A quarter of new jobs are projected for the healthcare and social assistance industries, and 1 in 6 for professional, scientific, and technical services. In almost all industries, employment of these workers are expected to grow more slowly than overall employment, due to continued office automation, including that related to electronic business, and as organizations make greater use of temporary workers employed by the employment services industry. Thirteen out of 30 occupations with the largest projected job declines, including word processors and typists; stock clerks and order fillers; and secretaries, except legal, medical, and executive, are in this group. (See table 5.) However, a number of personal-contact occupations, such as receptionists and information clerks, and bill and account collectors, are less affected by changing technology, and have relatively large projected growth.

Farming, fishing, and forestry occupations are projected to grow by 35,000 jobs. Self-employed are projected to decline 7.6 percent, with most declines among fishers and related fishing workers. (Agricultural managers, including farmers and ranchers, are classified with management, business, and financial occupations.)

The construction and extraction occupations major group is projected to add 1.1 million jobs, with 7 out of 10 in the construction industry. One new job in 9, and fastest growth, is projected for the employment services industry. A decline of 10,000 is projected for the mining industry—mostly for extraction workers. Self-employed construction and extraction workers are projected to increase slightly. Self-employed first-line supervisors/managers of construction trades and extraction workers (mostly contractors) are projected to increase, while self-employed carpenters are projected to decline.

Installation, maintenance, and repair occupations are projected to add 776,000 jobs. About 1 new job in 6 is projected for retail trade, which includes motor vehicle and parts dealers; 1 new job in 8 is projected for the construction industry, and 1 in 10, for automotive repair and maintenance. Self-employed workers in this group are projected to remain unchanged. Self-employed heating, air conditioning, and refrigeration mechanics and installers are projected to increase, but others are projected to decline.

Production occupations are expected to add 354,000 jobs. Most growth is projected for rapidly-growing employment services, which provides employees to other industries on a contract or fee basis, while some growth is projected for wholesale and retail trade. Manufacturing, which employed 7 out of 10 production workers in 2002, is projected to lose nearly 200,000 of these workers. Self-employed production workers are projected to decline 8.8 percent, with largest declines among apparel occupations and woodworkers.

Transportation and material moving occupations are projected to add 1.3 million jobs. More than 2 out of 5 new jobs should be in transportation and warehousing, and 1 in 4,

in employment services. Little change is projected for these workers in manufacturing, where 1 out of 6 was employed in 2002. Water transportation occupations are projected to grow slowly, while railroad occupations continue their long-term decline. Nearly half of new jobs should be for truck drivers and driver/sales workers. Little change is projected for self-employed transportation workers.

Detailed occupations

This section focuses in occupations that are the fastest growing, have the largest numeric increases, and have the largest numeric declines. Data on numeric and percent growth for nearly 700 detailed occupations are presented in table 2.

The growth rates for detailed occupations range from an increase of 59 percent for medical assistants to a decline of 56 percent for telephone operators. Numeric growth ranges from 623,000 additional jobs for registered nurses to a decline of 238,000 farmers and ranchers. The 30 occupations with the largest numeric increase (table 4) account for 44 percent of the 21.3-million total increase over the 2002–12 period. The 30 occupations that are projected as the fastest growing (table 3) have growth rates of 35 percent or greater, more than twice the average for all occupations or faster. Six occupations—three health related, two computer, and one education, are included in both groups—personal and home care aides; medical assistants; home health aides; computer software engineers, application; computer systems analysts; and postsecondary teachers.

Table 3. Fastest growing occupations, 2002–12

| | | Employ | yment | Cha | inge | Quartile | |
|------------------|--|--------|-------|--------|---------|--|---|

| 9-1122 | Occupational therapists | 82 | 110 | 29 | 35 | 1 | Bachelor's degree |
| 9-1126 | Respiratory therapists | 86 | 116 | 30 | 35 | 2 | Associate degree |

¹ The quartile rankings of Occupational Employment Statistics annual earnings data are presented in the following categories: 1=very high (\$41,820 and over), 2=high (\$27,500 to \$41,780), 3=low (\$19,710 to \$27,380), and 4=very low (up to \$19,600). The rankings were based on quartiles using one-fourth of total employment to define each quartile. Earnings are for wage and salary workers.

² An occupation is placed into one of 11 categories that best describes the education or training needed by most workers to become fully qualified. For more information about the categories, see *Occupational Projections and Training Data*, Bulletin 2572 (Bureau of Labor Statistics, forthcoming).

Table 4. Occupations with the largest job growth, 2002–12

[Numbers in thousands of jobs]

| | | Employment | | Change | | Quartile | |

¹ The quartile rankings of Occupational Employment Statistics annual earnings data are presented in the following categories: 1=very high (\$41,820 and over), 2=high (\$27,500 to \$41,780), 3=low (\$19,710 to \$27,380), and 4=very low (up to \$19,600). The rankings were based on quartiles using one-fourth of total employment to define each quartile. Earnings are for wage and salary workers.

Fastest growing occupations. Fifteen of the 30 fastest growing occupations are health related, 7 are computer-related occupations, 3 are teachers, and 3 are environment related. (See table 3.) The others are social and human services assistants, and fitness trainers and aerobics instructors.

The two healthcare groups discussed in the previous section—healthcare practitioners and technical occupations, and healthcare support occupations—have a combined growth rate of 28.8 percent. Rapid growth among health-related occupations reflects an aging population that requires more healthcare, a wealthier population that can afford better healthcare, and advances in medical technology that permit more health problems to be treated more aggressively. How-

ever, job growth among health-related occupations will be limited by efforts to control the rapid growth of spending on healthcare, both by private medical insurers and by government—to restrict the growth of Medicare and Medicaid reimbursements. Even so, continued efforts to control healthcare costs should stimulate some health-related occupations (mostly aides, assistants, and technicians) to grow even more rapidly than overall health employment. They will assume some duties formerly done by more highly paid healthcare workers, such as dentists, physicians, and therapists. These include dental assistants, dental hygienists, physician assistants, physical therapist assistants and aides, and occupational therapist assistants and aides. Some healthcare occu-

² An occupation is placed into one of 11 categories that best describes the education or training needed by most workers to become fully qualified. For more information about the categories, see *Occupational Projections and Training Data*, Bulletin 2572 (Bureau of Labor Statistics, forthcoming).

pations also will grow more rapidly than overall healthcare employment because they are more likely to provide services to the rapidly growing older population. These include some listed above, such as physical and occupational therapist assistants and aides, as well as physical therapists, occupational therapists, and respiratory therapists. Employment of medical assistants should grow the fastest of any occupation, as they perform an increasing share of administrative and clinical duties in rapidly-growing offices of physicians.

The number of medical records and health information technicians employed also is expected to grow rapidly due to the need to maintain records for an increasing number of medical tests, treatments, and procedures that will undergo greater scrutiny by third-party payers, regulators, courts, and consumers. Employment of home health aides and of personal and home care aides (included in this discussion of healthrelated occupations but classified as a personal service occupation in table 2) also should be stimulated, as the older population grows and as efforts to contain healthcare costs continue. The older population is more likely to need in-home healthcare, as well as personal care and housekeeping that these workers provide. In addition, patients of all ages are being discharged from hospitals and nursing facilities as early as possible. These aides also provide care to this rapidly growing group of patients. Employment of veterinary technologists and technicians, also classified as a healthcare occupation, is projected to grow rapidly as pet owners spend more on advanced animal care services, such as preventive dental care and surgical procedures.

The increasing demand for computer-related occupations reflects the rapid advances in computer technology and the continuing development of new computer applications, including the Internet and Intranets. Overall, computer specialists, a component of computer and mathematical occupations, is projected to grow 35.8 percent; and computer and information systems managers—classified within management, business, and financial occupations—is projected to grow 36.1 percent. (See table 2.) Two computer-related occupations also are among the occupations with the largest projected numerical job growth. (See table 4).

Employment of environmental engineers; environmental science and protection technicians, including health; and hazardous material removal workers will be stimulated by a need to met environmental regulations, develop methods of cleaning up existing hazards, and, more generally, respond to increasing public concern for a safe and clean environment.

Employment of postsecondary school teachers is projected to grow as the population of 18- to 24-year-olds increases and as more adults return to college, but the number of tenure-track positions is expected to decline as institutions seek flexibility in dealing with financial matters and changing student interests. Employment of preschool teachers, except

special education, should grow as the proportion of preschoolage children attending school increases, while employment of self-enrichment education teachers is expected to grow as more people embrace lifelong learning, particularly retired baby boomers.

Fitness trainers and aerobics instructors are projected to grow rapidly, due to rising interest in personal training, aerobics classes, and other fitness activities. Social and human service assistants are projected to grow rapidly as employers attempt to control costs in the face of rapid growth in demand for services. Social service agencies are restructuring services and hiring more lower-paid social and human service assistants instead of social workers.

Twenty-one of the 30 fastest growing occupations generally require a postsecondary vocational award or a degree.⁷ This is consistent with growth rates by major group presented in the previous section. The fastest growing group, professional and related, is made up mostly of occupations that generally require this level of education. Thirteen of the fastest growing occupations are concentrated in the first earnings quartile and eight in the third earnings quartile.

Occupations with the largest job growth. Very large occupations with average or even below-average growth rates provide many job openings, as do very fast growing ones with smaller base-year employment. These 30 occupations shown on table 4 are from a much broader range of occupational groups than are the 30 fastest growing. Five are health related, and six are service occupations other than those related to health, including three in food service and two in building and grounds cleaning and maintenance occupations. Four each are in education, training, and library, and in sales and related occupations. Three each are in management, business, and financial, and in office and administrative support occupations; and two each are in computer and mathematical, and in transportation and material moving major occupation groups; one is installation, maintenance, and repair.

Twenty-one of the 30 had 2002 employment of 1 million or more. Of the others, seven have projected growth at least twice the 14.8-percent average for all occupations. The three largest occupations in 2002, each with employment of 3 million or more, are projected to grow more slowly than the total for all occupations.

Registered nurses and nursing aides, orderlies, and attendants—by far the two largest health-related occupations in 2002—are projected to have more numerical growth than any other health-related occupations. Home health aides, medical assistants, and personal and home care aides, all among the 30 fastest growing, are also on this list. The four largest education, training, and library occupations in 2002—postsecondary teachers; elementary school teachers, except special education; teachers assistants; and secondary school

teachers, except special and vocational education—are also among the top 30 occupations. Of the four sales and related occupations: retail salespersons and cashiers, except gaming are projected to grow about as fast as the average for all occupations; while sales representatives, wholesale and manufacturing, except technical and scientific products are projected to grow somewhat faster. First-line supervisors/managers of retail sales workers are projected to grow relatively slowly, with a 9.7-percent decline among the self-employed (owners of stores and other retail businesses).

Management analysts and security guards are projected to grow about twice as fast as the average for all occupations, while accountants and auditors and general and operations managers should grow somewhat faster than the average. The list has three food-service occupations—combined food preparation and serving workers, including fast food and waiters and waitersess, have base-year employment of about 2 million, while

food preparation workers has 850,000. Of the two transportation and material moving occupations: truck drivers, heavy and tractor trailer; and truck drivers, light and delivery services, are projected to grow 19 and 23 percent, respectively. Among building and grounds cleaning and maintenance occupations, janitors and cleaners is projected to have more openings than landscaping and groundskeeping workers, even though the latter is projected to grow faster. Of the three office and administrative support occupations, customer service representatives and receptionists and information clerks are projected to grow rapidly, while office clerks, general, with employment of 3 million, is projected to grow relatively slowly.

Half of the 30 occupations with the largest numerical job growth are in the short-term on-the-job training category, and 9 are in the associate or higher degree category. Of those with the largest numeric increases, 9 are in the first, and 10 are in the fourth earnings quartile.

Table 5. Occupations with the largest job decline, 2002–12

| | | Employment | | Change | | Quartile | |
|--|---|------------|-------|--------|---------|--|---|

¹ The quartile rankings of Occupational Employment Statistics annual earnings data are presented in the following categories: 1=very high (\$41,820 and over), 2=high (\$27,500 to \$41,780), 3=low (\$19,710 to \$27,380), and 4=very low (up to \$19,600). The rankings were based on quartiles using one-fourth of total employment to define each quartile. Earnings are for wage and salary workers.

² An occupation is placed into one of 11 categories that best describes the education or training needed by most workers to become fully qualified. For more information about the categories, see *Occupational Projections and Training Data*, Bulletin 2572 (Bureau of Labor Statistics, forthcoming).

Declining occupations. This section of the article focuses just on those occupations with the largest numerical job declines because many detailed occupations with the fastest rates of decline are small, with very small employment declines. (See table 5.) Thirteen of the occupations with the largest declines are office and administrative support, 11 are production, and 3 are sales and related. Others are farmers and ranchers, fishers and related fishing workers, and announcers. Changes in technology or business practices will reduce the demand for most of the 30 occupations.

Advances in computer, optical scanning, and voice recognition technologies and growth in electronic business will reduce demand for word processors and typists; stock clerks and order fillers; secretaries, except legal, medical, and executive; telephone operators; postal service mail sorters, processors, and processing machine operators; loan interviewers and clerks; data entry keyers; order clerks; and other office and administrative support occupations.8 Advances in technology, such as faster machines and more automated processes, and a shift of assembly and other production activities to other countries will lower employment for electrical and electronic equipment assemblers, team assemblers, chemical plant and systems operators, and mixing and blending machine workers. Prepress technicians and workers also will be affected as electronic publishing and printing-on-demand limit the production of printed material.

Employment in the textile and apparel industries will decline, due to greater imports—as import quotas are lifted—and to improved production technology. This will cause employment declines for sewing machine operators; sewers, hand; and the four textile machine operator occupations listed on table 5. Farmers and ranchers will decline as market pressures cause farm consolidation and as farm technology improves.

Employment of travel agents should decline as more travelers rely on the Internet to book travel. Telemarketers will decrease as more people opt out of receiving calls and as blocking technology improves. Door-to-door sales workers, news and street vendors, and related workers will decline due to competition from stores and on-line outlets. Radio and television station consolidation and improved editing and other off-air technologies are expected to lower employment of announcers. Fishers and related workers are projected to decline as the stock of fish decreases and the technology for finding fish improves.

Thirteen of the 30 occupations with the largest numerical declines were in the moderate-term on-the-job training category, 11 were in the short-term category, and none were in a degree category. Of the largest declines, 9 are in the second earnings quartile, and 16 are in the third earnings quartile.

Total job openings

In addition to occupational employment growth, another aspect of the demand for workers is the need to replace those who leave their jobs to enter other occupations, retire, or leave the labor force for other reasons. Job openings resulting from replacement needs are very important because, in most occupations, they exceed those resulting from employment growth. Even occupations that are projected to decline provide some job openings—for example, farmers and ranchers and aerospace engineers. (See table 2.)

The measure of replacement needs is complex because of the continuous movement of workers into and out of occupations. The replacement needs cited in this article are based on the net change in employment (entrants minus separations) in each age cohort over the projection period. Although this measure understates the total number of job openings in an occupation, it best represents the job openings for new labor force entrants over the projection period.⁹

Over the 2002–12 period, more job openings are expected to result from replacement needs (35 million) than from employment growth in the economy (21.3 million). Service occupations are projected to have the most total job openings, 13 million. The number of job openings due to net replacement needs should exceed the number due to growth in major groups with average or below-average projected growth, as well as those among service occupations, which includes many occupations with high turnover. Food preparation and serving occupations have particularly high replacement needs. However, healthcare support occupations should have only half as many replacement openings as growth openings.

The only major group with fewer openings from replacement needs than from employment growth is professional and related occupations, the fastest growing. Even within this group, however, replacement openings exceed growth openings in three subgroups—architecture and engineering; life, physical, and social scientists; and arts, design, entertainment, sports, and media occupations.

Notes

the 2004–05 Handbook, BLS Bulletin 2570, should be available in Spring 2004. Job outlook information in the 2004–05 Handbook will use the projections presented in each of the articles in this issue of the Monthly Labor Review. For a description of the methodology used to develop employment projections, see BLS Handbook of Methods, Bulletin 2490 (Bureau of Labor Statistics, April 1997), pp. 122–29.

¹ Occupational projections presented in this article provide information to those interested in labor market issues. They also provide the background for analyses of future employment opportunities described in the forthcoming 2004–05 Occupational Outlook Handbook. The Internet version of this edition of the Handbook, which will be accessible at http://www.bls.gov/oco/, is expected to be available in late February 2004; the print version of

- ² Occupational data reflect the 2000 Standard Occupational Classification system. Base year employment data were developed using the 2002 Occupational Employment Statistics Survey, supplemented with data from the Current Population Survey for selfemployed and unpaid family workers.
- ³ The Bureau has recently shifted to the 2002 North American Industry Classification System (NAICS). Industry data in this article reflect this shift. The NAICS classification will also be used in an article on high technology in a forthcoming issue of the *Review*. The article will update *High-technology employment: a broader view*, which appeared in the June 1999 *Review*.
- ⁴ Previous occupational projections articles in the *Review* included State and local government education employment and hospital employment in the education services and health services industries, respectively. This article includes them with government—as do industry output and employment projections articles in this and earlier issues of the *Review*.
 - 5 Ibid.
- ⁶ Daniel E. Hecker, "Employment impact of electronic business," *Monthly Labor Review*, May 2001, p. 5.
- ⁷ Education and training categories listed in tables 3, 4, and 5 show the category that best describes the education or training needed by most workers to become fully qualified. However, for many occupations there are other sources of education and training, as well. Data from the Bureau's Current Population Survey show that for most occupations, workers have a variety of education levels. More detail on education and training is available in the Occupational Outlook Handbook; more on education and training categories is available in Occupational Projections and Training Data, Bulletin 2572 (Bureau of Labor Statistics, forthcoming). Also, see footnote 1.
 - 8 Hecker, "Employment impact..."
- ⁹ Net separations do not count all movements of workers out of an occupation, which is a measure termed total separations. For example, an opening caused by a worker who stops working for a period and then gets another job in his or her previous occupation would be counted in the measure of total separations but not net separations. See the discussion on the uses of replacement needs information developed in *Occupational Projections and Training Data*, Bulletin 2572 (Bureau of Labor Statistics, forthcoming).

Trade and the city

International trade is most often accounted for in national terms. There are some data available on exports from specific metropolitan areas and there have been occasional efforts to allocate imports regionally, generally at a very broad level of geographic detail. In the fourth quarter 2003 issue of the Federal Reserve Bank of Chicago's *Economic Perspective*, William Testa, Thomas Klier, and Alexei Zelnev seek to measure the degree of international import and export competition faced by manufacturers in the largest American cities.

Their crudest measure of import competition is total imports attributed to the metropolitan area as a percent of their estimate of gross metropolitan product. Using this metric, the Detroit-Ann Arbor-Flint area has the highest level of import competition at 19 percent, Washington-Baltimore the lowest at 2.1 percent, while Cleveland-Akron and San Diego straddle the average of about 9.5 percent.

Another measure—import penetration—is a more specific way to reflect the competition faced by an area's manufacturing industries. As the authors describe the concept, "Import penetration measures the ratio of imports for a particular industry to the sum of imports plus that portion of domestic production that is *not* exported abroad. ... [T]his measure of import penetration shows the share of domestic sales of a good that is imported rather than domestically produced."

When the measure of import penetration is aggregated across all local manufacturing industries, the metropolitan areas facing the highest import penetration are San Diego, San Francisco-Oakland-San Jose, Boston-Worcester-Lawrence, and Portland-Salem. Facing the lowest penetration are Kansas City, Washington-Baltimore, Atlanta, and Sacramento-Yolo.

Testa and his colleagues also provide a measure of export intensity—exports as a percent of gross metropolitan product. The most export

intensive metropolitan areas are Seattle-Tacoma-Bremerton, Detroit-Ann Arbor-Flint, and Miami-Ft. Lauderdale. The least export intensive areas were Denver-Boulder, Kansas City, and Washington-Baltimore.

Europe's shorter work years

Workers in France and Germany work fewer hours in a year than do Americans—the equivalent of 6 to 9 regular workweeks fewer, according to International Labor Organization figures cited by Douglas Clement, editor of the Federal Reserve Bank of Minneapolis quarterly, *The Region*. Writing in the December 2003 issue, Clement outlines the somewhat controversial explanation of this phenomenon offered by Professor Edward C. Prescott of Arizona State University (and a senior monetary advisor to the Minneapolis Fed).

While many analysts look to cultural and legal difference between the United States and Europe (see the August 2003 issue's Précis for an example of the latter), Prescott believes that European workers are simply responding to a different set of economic incentives than are Americans. Clement cites Prescott: "French, Japanese, and U.S. workers all have similar preferences. The French are not better at enjoying leisure. The Japanese are not compulsive savers." The reason the average French worker spends about 6 weeks fewer at work than does the average American instead comes down to the fact that the tax system in France, and many other European countries, drives a much larger wedge between what a worker earns and what that worker gets to keep after taxes.

Prescott's work has highlighted the importance of understanding the relative prices of consumption and leisure, continues Clement. That set of relative prices is determined by the tax rate on consumption—sales taxes, excises,

property taxes, and so forth,—and the taxes on labor-income taxes, social insurance taxes, and the like. While none of this seems particularly controversial, Prescott's introduction of the concepts into a standard growth accounting model has attracted some skeptics. Although the results of the model seem to produce a fairly good representation of reality-predicted hours worked per week were very close for Germany and the United Kingdom, a little low for the North American economies, and a bit high for others-Clement cites Peter Lindert of the University of California at Davis as seeing the work as "a theoretical model, heavily laden with assumptions. ... educated, intelligent, plausible fiction."

On the other hand, Clement summarizes the results of an econometric study by labor economists Steven Davis (University of Chicago) and Magnus Henrekson (Stockholm School of Economics) that found that a 12.8-percentage point difference in tax rates results in 122 fewer hours supplied per worker and about a 5-percentage point decrease in the employment to population ratio.

Human capital on the hoof

As we pointed out in our October 2003 Précis of work by Paul D. Gottlieb and Michael Fogarty, retaining or attracting college graduates to an area can have a positive impact on average per capita income for that area. Thus, the recent examination in the Federal Reserve Bank of Cleveland's Economic Trends of the migration patterns of college graduates may be of interest. As it turns out, the highest State retention rates in 2001 of graduates in the Class of 2000 were in Idaho, Maine, Texas, California, and New Jersey. The lowest retention rates were in Delaware, Vermont, Rhode Island, North Dakota, and Iowa.

Notes on Current Labor Statistics

This section of the *Review* presents the principal statistical series collected and calculated by the Bureau of Labor Statistics: series on labor force; employment; unemployment; labor compensation; consumer, producer, and international prices; productivity; international comparisons; and injury and illness statistics. In the notes that follow, the data in each group of tables are briefly described; key definitions are given; notes on the data are set forth; and sources of additional information are cited.

General notes

The following notes apply to several tables in this section:

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect on the data of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might prevent short-term evaluation of the statistical series. Tables containing data that have been adjusted are identified as "seasonally adjusted." (All other data are not seasonally adjusted.) Seasonal effects are estimated on the basis of current and past experiences. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years.

Seasonally adjusted data appear in tables 1–14, 16–17, 43, and 47. Seasonally adjusted labor force data in tables 1 and 4–9 were revised in the February 2004 issue of the *Review*. Seasonally adjusted establishment survey data shown in tables 1, 12–14 and 16–17 were revised in the July 2003 *Review*. A brief explanation of the seasonal adjustment methodology appears in "Notes on the data."

Revisions in the productivity data in table 49 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month-to-month and quarter-to-quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average All-Items CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data—such as the "real" earnings shown in table 14—are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current-dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100. For example, given a current hourly wage rate of \$3 and a current price

index number of 150, where 1982 = 100, the hourly rate expressed in 1982 dollars is \$2 (\$3/150 x 100 = \$2). The \$2 (or any other resulting values) are described as "real," "constant," or "1982" dollars.

Sources of information

Data that supplement the tables in this section are published by the Bureau in a variety of sources. Definitions of each series and notes on the data are contained in later sections of these Notes describing each set of data. For detailed descriptions of each data series, see BLS Handbook of Methods, Bulletin 2490. Users also may wish to consult Major Programs of the Bureau of Labor Statistics, Report 919. News releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule appearing on the back cover of this issue.

More information about labor force, employment, and unemployment data and the household and establishment surveys underlying the data are available in the Bureau's monthly publication, *Employment and Earnings*. Historical unadjusted and seasonally adjusted data from the household survey are available on the Internet:

http://www.bls.gov/cps/

Historically comparable unadjusted and seasonally adjusted data from the establishment survey also are available on the Internet:

http://www.bls.gov/ces/

Additional information on labor force data for areas below the national level are provided in the BLS annual report, *Geographic Profile of Employment and Unemployment*.

For a comprehensive discussion of the Employment Cost Index, see Employment Cost Indexes and Levels, 1975–95, BLS Bulletin 2466. The most recent data from the Employee Benefits Survey appear in the following Bureau of Labor Statistics bulletins: Employee Benefits in Medium and Large Firms; Employee Benefits in Small Private Establishments; and Employee Benefits in State and Local Governments.

More detailed data on consumer and producer prices are published in the monthly periodicals, *The CPI Detailed Report* and *Producer Price Indexes*. For an overview of the 1998 revision of the CPI, see the December 1996 issue of the *Monthly Labor Review*. Additional data on international prices appear in monthly news releases.

Listings of industries for which productivity indexes are available may be found on the Internet:

http://www.bls.gov/lpc/

For additional information on interna-

tional comparisons data, see *International Comparisons of Unemployment*, BLS Bulletin 1979.

Detailed data on the occupational injury and illness series are published in *Occupa*tional Injuries and Illnesses in the United States, by Industry, a BLS annual bulletin.

Finally, the *Monthly Labor Review* carries analytical articles on annual and longer term developments in labor force, employment, and unemployment; employee compensation and collective bargaining; prices; productivity; international comparisons; and injury and illness data.

Symbols

n.e.c. = not elsewhere classified.

n.e.s. = not elsewhere specified.

 preliminary. To increase the timeliness of some series, preliminary figures are issued based on representative but incomplete returns.

 r = revised. Generally, this revision reflects the availability of later data, but also may reflect other adjustments.

Comparative Indicators

(Tables 1-3)

Comparative indicators tables provide an overview and comparison of major BLS statistical series. Consequently, although many of the included series are available monthly, all measures in these comparative tables are presented quarterly and annually.

Labor market indicators include employment measures from two major surveys and information on rates of change in compensation provided by the Employment Cost Index (ECI) program. The labor force participation rate, the employment-population ratio, and unemployment rates for major demographic groups based on the Current Population ("household") Survey are presented, while measures of employment and average weekly hours by major industry sector are given using nonfarm payroll data. The Employment Cost Index (compensation), by major sector and by bargaining status, is chosen from a variety of BLS compensation and wage measures because it provides a comprehensive measure of employer costs for hiring labor, not just outlays for wages, and it is not affected by employment shifts among occupations and in-

Data on changes in compensation,

prices, and productivity are presented in table 2. Measures of rates of change of compensation and wages from the Employment Cost Index program are provided for all civilian nonfarm workers (excluding Federal and household workers) and for all private nonfarm workers. Measures of changes in consumer prices for all urban consumers; producer prices by stage of processing; overall prices by stage of processing; and overall export and import price indexes are given. Measures of productivity (output per hour of all persons) are provided for major sectors.

Alternative measures of wage and compensation rates of change, which reflect the overall trend in labor costs, are summarized in table 3. Differences in concepts and scope, related to the specific purposes of the series.

contribute to the variation in changes among the individual measures.

Notes on the data

Definitions of each series and notes on the data are contained in later sections of these notes describing each set of data.

Employment and Unemployment Data

(Tables 1; 4-24)

Household survey data Description of the series

EMPLOYMENT DATA in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 60,000 households selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

Definitions

Employed persons include (1) all those who worked for pay any time during the week which includes the 12th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who

did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding 4 weeks. Persons who did not look for work because they were on layoff are also counted among the unemployed. The unemployment rate represents the number unemployed as a percent of the civilian labor force.

The civilian labor force consists of all employed or unemployed persons in the civilian noninstitutional population. Persons not in the labor force are those not classified as employed or unemployed. This group includes discouraged workers, defined as persons who want and are available for a job and who have looked for work sometime in the past 12 months (or since the end of their last job if they held one within the past 12 months), but are not currently looking, because they believe there are no jobs available or there are none for which they would qualify. The civilian noninstitutional population comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy. The civilian labor force participation rate is the proportion of the civilian noninstitutional population that is in the labor force. The employment-population ratio is employment as a percent of the civilian noninstitutional population.

Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the intercensal years. These adjustments affect the comparability of historical data. A description of these adjustments and their effect on the various data series appears in the Explanatory Notes of Employment and Earnings. For a discussion of changes introduced in January 2003, see "Revisions to the Current Population Survey Effective in January 2003" in the February 2003 issue of Employment and Earnings (available on the BLS Web site at: http://www.bls.gov/cps/rvcps03.pdf).

Effective in January 2003, BLS began using the X-12 ARIMA seasonal adjustment program to seasonally adjust national labor force data. This program replaced the X-11 ARIMA program which had been used since January 1980. See "Revision of Seasonally Adjusted Labor Force Series in 2003," in the February 2003 issue of *Employment and Earnings* (available on the BLS Web site at http:www.bls.gov/cps/cpsrs.pdf) for a discussion of the introduction of the use of X-

12 ARIMA for seasonal adjustment of the labor force data and the effects that it had on the data.

At the beginning of each calendar year, historical seasonally adjusted data usually are revised, and projected seasonal adjustment factors are calculated for use during the January–June period. The historical seasonally adjusted data usually are revised for only the most recent 5 years. In July, new seasonal adjustment factors, which incorporate the experience through June, are produced for the July–December period, but no revisions are made in the historical data.

FOR ADDITIONAL INFORMATION on national household survey data, contact the Division of Labor Force Statistics: (202) 691–6378.

Establishment survey data

Description of the series

EMPLOYMENT, HOURS, AND EARNINGS DATA in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by about 160,000 businesses and government agencies, which represent approximately 400,000 individual worksites and represent all industries except agriculture. The active CES sample covers approximately one-third of all nonfarm payroll workers. Industries are classified in accordance with the 2002 North American Industry Classification System. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

Definitions

An **establishment** is an economic unit which produces goods or services (such as a factory or store) at a single location and is engaged in one type of economic activity.

Employed persons are all persons who received pay (including holiday and sick pay) for any part of the payroll period including the 12th day of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in the goods-producing industries cover employees, up through the level of working supervisors, who engage directly in the manufacture or construction of the establishment's product. In private service-providing industries, data are collected for nonsupervisory workers, which include most employees except those in executive, managerial, and supervisory positions. Those workers mentioned in tables 11-16 include production workers in manufacturing and natural resources and mining; construction workers in construction; and nonsupervisory workers in all private service-providing industries. Production and nonsupervisory workers account for about four-fifths of the total employment on private nonagricultural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. Real earnings are earnings adjusted to reflect the effects of changes in consumer prices. The deflator for this series is derived from the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W).

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received, and are different from standard or scheduled hours. Overtime hours represent the portion of average weekly hours which was in excess of regular hours and for which overtime premiums were paid.

The **Diffusion Index** represents the percent of industries in which employment was rising over the indicated period, plus one-half of the industries with unchanged employment; 50 percent indicates an equal balance between industries with increasing and decreasing employment. In line with Bureau practice, data for the 1-, 3-, and 6-month spans are seasonally adjusted, while those for the 12-month span are unadjusted. Table 17 provides an index on private nonfarm employment based on 278 industries, and a manufacturing index based on 84 industries. These indexes are useful for measuring the dispersion of economic gains or losses and are also economic indicators.

Notes on the data

Establishment survey data are annually adjusted to comprehensive counts of employment (called "benchmarks"). The March 2002 benchmark was introduced in June 2003 with the release of data for May 2003, published in the July 2003 issue of the *Review*. With the release in June, CES completed a conversion from the Standard Industrial Classification (SIC) system to the North American Industry Classification System (NAICS) and completed the transition from its original quota sample de-

sign to a probability-based sample design. The industry-coding update included reconstruction of historical estimates in order to preserve time series for data users. Normally 5 years of seasonally adjusted data are revised with each benchmark revision. However, with this release, the entire new time series history for all CES data series were re-seasonally adjusted due to the NAICS conversion, which resulted in the revision of all CES time series.

Also in June 2003, the CES program introduced concurrent seasonal adjustment for the national establishment data. Under this methodology, the first preliminary estimates for the current reference month and the revised estimates for the 2 prior months will be updated with concurrent factors with each new release of data. Concurrent seasonal adjustment incorporates all available data, including first preliminary estimates for the most current month, in the adjustment process. For additional information on all of the changes introduced in June 2003, see the the June 2003 issue of Employment and Earnings and "Recent changes in the national Current Employment Statistics survey," Monthly Labor Review, June 2003, pp. 3-13.

Revisions in State data (table 11) occurred with the publication of January 2003 data. For information on the revisions for the State data, see the March and May 2003 issues of *Employment and Earnings*, and "Recent changes in the State and Metropolitan Area CES survey," *Monthly Labor Review*, June 2003, pp. 14–19.

Beginning in June 1996, the BLS uses the X-12-ARIMA methodology to seasonally adjust establishment survey data. This procedure, developed by the Bureau of the Census, controls for the effect of varying survey intervals (also known as the 4- versus 5-week effect), thereby providing improved measurement of over-the-month changes and underlying economic trends. Revisions of data, usually for the most recent 5-year period, are made once a year coincident with the benchmark revisions.

In the establishment survey, estimates for the most recent 2 months are based on incomplete returns and are published as preliminary in the tables (12–17 in the *Review*). When all returns have been received, the estimates are revised and published as "final" (prior to any benchmark revisions) in the third month of their appearance. Thus, December data are published as preliminary in January and February and as final in March. For the same reasons, quarterly establishment data (table 1) are preliminary for the first 2 months of publication and final in the third month. Thus, fourthquarter data are published as preliminary in January and February and as final in March.

FOR ADDITIONAL INFORMATION on establishment survey data, contact the Division of

Current Employment Statistics: (202) 691-6555.

Unemployment data by State

Description of the series

Data presented in this section are obtained from the Local Area Unemployment Statistics (LAUS) program, which is conducted in cooperation with State employment security agencies.

Monthly estimates of the labor force, employment, and unemployment for States and sub-State areas are a key indicator of local economic conditions, and form the basis for determining the eligibility of an area for benefits under Federal economic assistance programs such as the Job Training Partnership Act. Seasonally adjusted unemployment rates are presented in table 10. Insofar as possible, the concepts and definitions underlying these data are those used in the national estimates obtained from the CPS.

Notes on the data

Data refer to State of residence. Monthly data for all States and the District of Columbia are derived using standardized procedures established by BLS. Once a year, estimates are revised to new population controls, usually with publication of January estimates, and benchmarked to annual average CPS levels.

FOR ADDITIONAL INFORMATION on data in this series, call (202) 691–6392 (table 10) or (202) 691–6559 (table 11).

Covered employment and wage data (ES-202)

Description of the series

EMPLOYMENT, WAGE, AND ESTABLISHMENT DATA in this section are derived from the quarterly tax reports submitted to State employment security agencies by private and State and local government employers subject to State unemployment insurance (UI) laws and from Federal, agencies subject to the Unemployment Compensation for Federal Employees (UCFE) program. Each quarter, State agencies edit and process the data and send the information to the Bureau of Labor Statistics.

The Covered Employment and Wages data, also referred as ES-202 data, are the most complete enumeration of employment and wage information by industry at the national, State, metropolitan area, and county levels. They have broad economic significance in evaluating labor market trends and major industry developments.

Definitions

In general, ES-202 monthly employment data represent the number of covered workers who worked during, or received pay for, the pay period that included the 12th day of the month. Covered private industry employment includes most corporate officials, executives, supervisory personnel, professionals, clerical workers, wage earners, piece workers, and part-time workers. It excludes proprietors, the unincorporated self-employed, unpaid family members, and certain farm and domestic workers. Certain types of nonprofit employers, such as religious organizations, are given a choice of coverage or exclusion in a number of States. Workers in these organizations are, therefore, reported to a limited degree.

Persons on paid sick leave, paid holiday, paid vacation, and the like, are included. Persons on the payroll of more than one firm during the period are counted by each UI-subject employer if they meet the employment definition noted earlier. The employment count excludes workers who earned no wages during the entire applicable pay period because of work stoppages, temporary layoffs, illness, or unpaid vacations.

Federal employment data are based on reports of monthly employment and quarterly wages submitted each quarter to State agencies for all Federal installations with employees covered by the Unemployment Compensation for Federal Employees (UCFE) program, except for certain national security agencies, which are omitted for security reasons. Employment for all Federal agencies for any given month is based on the number of persons who worked during or received pay for the pay period that included the 12th of the month.

An establishment is an economic unit, such as a farm, mine, factory, or store, that produces goods or provides services. It is typically at a single physical location and engaged in one, or predominantly one, type of economic activity for which a single industrial classification may be applied. Occasionally, a single physical location encompasses two or more distinct and significant activities. Each activity should be reported as a separate establishment if separate records are kept and the various activities are classified under different four-digit sic codes.

Most employers have only one establishment; thus, the establishment is the predominant reporting unit or statistical entity for reporting employment and wages data. Most employers, including State and local governments who operate more than one establishment.

ment in a State, file a Multiple Worksite Report each quarter, in addition to their quarterly UI report. The Multiple Worksite Report is used to collect separate employment and wage data for each of the employer's establishments, which are not detailed on the ur report. Some very small multi-establishment employers do not file a Multiple Worksite Report. When the total employment in an employer's secondary establishments (all establishments other than the largest) is 10 or fewer, the employer generally will file a consolidated report for all establishments. Also, some employers either cannot or will not report at the establishment level and thus aggregate establishments into one consolidated unit, or possibly several units, though not at the establishment level.

For the Federal Government, the reporting unit is the installation: a single location at which a department, agency, or other government body has civilian employees. Federal agencies follow slightly different criteria than do private employers when breaking down their reports by installation. They are permitted to combine as a single statewide unit: 1) all installations with 10 or fewer workers, and 2) all installations that have a combined total in the State of fewer than 50 workers. Also, when there are fewer than 25 workers in all secondary installations in a State, the secondary installations may be combined and reported with the major installation. Last, if a Federal agency has fewer than five employees in a State, the agency headquarters office (regional office, district office) serving each State may consolidate the employment and wages data for that State with the data reported to the State in which the headquarters is located. As a result of these reporting rules, the number of reporting units is always larger than the number of employers (or government agencies) but smaller than the number of actual establishments (or installations).

Data reported for the first quarter are tabulated into **size** categories ranging from worksites of very small size to those with 1,000 employees or more. The size category is determined by the establishment's March employment level. It is important to note that each establishment of a multi-establishment firm is tabulated separately into the appropriate size category. The total employment level of the reporting multi-establishment firm is not used in the size tabulation.

Covered employers in most States report total wages paid during the calendar quarter, regardless of when the services were performed. A few State laws, however, specify that wages be reported for, or based on the period during which services are performed rather than the period during which compensation is paid. Under most State laws or regulations, wages include bonuses, stock options, the cash value of meals and lodging, tips

and other gratuities, and, in some States, employer contributions to certain deferred compensation plans such as 401(k) plans.

Covered employer contributions for old-age, survivors, and disability insurance (OASDI), health insurance, unemployment insurance, workers' compensation, and private pension and welfare funds are not reported as wages. Employee contributions for the same purposes, however, as well as money withheld for income taxes, union dues, and so forth, are reported even though they are deducted from the worker's gross pay.

Wages of covered Federal workers represent the gross amount of all payrolls for all pay periods ending within the quarter. This includes cash allowances, the cash equivalent of any type of remuneration, severance pay, withholding taxes, and retirement deductions. Federal employee remuneration generally covers the same types of services as for workers in private industry.

Average annual wages per employee for any given industry are computed by dividing total annual wages by annual average employment. A further division by 52 yields average weekly wages per employee. Annual pay data only approximate annual earnings because an individual may not be employed by the same employer all year or may work for more than one employer at a time.

Average weekly or annual pay is affected by the ratio of full-time to part-time workers as well as the number of individuals in highpaying and low-paying occupations. When average pay levels between States and industries are compared, these factors should be taken into consideration. For example, industries characterized by high proportions of parttime workers will show average wage levels appreciably less than the weekly pay levels of regular full-time employees in these industries. The opposite effect characterizes industries with low proportions of part-time workers, or industries that typically schedule heavy weekend and overtime work. Average wage data also may be influenced by work stoppages, labor turnover rates, retroactive payments, seasonal factors, bonus payments, and so on.

Notes on the data

Beginning with the release of data for 2001, publications presenting data from the Covered Employment and Wages (CEW) program have switched to the 2002 version of the North American Industry Classification System (NAICS) as the basis for the assignment and tabulation of economic data by industry. NAICS is the product of a cooperative effort on the part of the statistical agencies of the United States, Canada, and Mexico. Due to difference in NAICS and Stan-

dard Industrial Classification (SIC) structures, industry data for 2001 is not comparable to the SIC-based data for earlier years.

Effective January 2001, the CEW program began assigning Indian Tribal Councils and related establishments to local government ownership. This BLS action was in response to a change in Federal law dealing with the way Indian Tribes are treated under the Federal Unemployment Tax Act. This law requires federally recognized Indian Tribes to be treated similarly to State and local governments. In the past the CEW program coded Indian Tribal Councils and related establishments in the private sector. As a result of the new law, CEW data reflects significant shifts in employment and wages between the private sector and local government from 2000 to 2001. Data also reflect industry changes. Those accounts previously assigned to civic and social organizations were assigned to tribal governments. There were no required industry changes for related establishments owned by these Tribal Councils. These tribal business establishments continued to be coded according to the economic activity of that entity.

To insure the highest possible quality of data, State employment security agencies verify with employers and update, if necessary, the industry, location, and ownership classification of all establishments on a 3-year cycle. Changes in establishment classification codes resulting from the verification process are introduced with the data reported for the first quarter of the year. Changes resulting from improved employer reporting also are introduced in the first quarter. For these reasons, some data, especially at more detailed geographic levels, may not be strictly comparable with earlier years.

The 2000 county data used to calculate the 2000–2001 changes were adjusted for changes in industry and county classification to make them comparable to data for 2001. As a result, the adjusted 2000 data differ to some extent from the data available on the Internet at:

http://www.bls.gov/cew/home.htm.

County definitions are assigned according to Federal Information Processing Standards Publications as issued by the National Institute of Standards and Technology. Areas shown as counties include those designated as independent cities in some jurisdictions and, in Alaska, those areas designated by the Census Bureau where counties have not been created. County data also are presented for the New England States for comparative purposes, even though townships are the more common designation used in New England

(and New Jersey).

For additional information on the covered employment and wage data, contact the Division of Administrative Statistics and Labor Turnover at (202) 691–6567.

Compensation and Wage Data

(Tables 1-3; 25-31)

COMPENSATION AND WAGE DATA are gathered by the Bureau from business establishments, State and local governments, labor unions, collective bargaining agreements on file with the Bureau, and secondary sources.

Employment Cost Index

Description of the series

The Employment Cost Index (ECI) is a quarterly measure of the rate of change in compensation per hour worked and includes wages, salaries, and employer costs of employee benefits. It uses a fixed market basket of labor—similar in concept to the Consumer Price Index's fixed market basket of goods and services—to measure change over time in employer costs of employing labor.

Statistical series on total compensation costs, on wages and salaries, and on benefit costs are available for private nonfarm workers excluding proprietors, the self-employed, and household workers. The total compensation costs and wages and salaries series are also available for State and local government workers and for the civilian nonfarm economy, which consists of private industry and State and local government workers combined. Federal workers are excluded.

The Employment Cost Index probability sample consists of about 4,400 private nonfarm establishments providing about 23,000 occupational observations and 1,000 State and local government establishments providing 6,000 occupational observations selected to represent total employment in each sector. On average, each reporting unit provides wage and compensation information on five well-specified occupations. Data are collected each quarter for the pay period including the 12th day of March, June, September, and December.

Beginning with June 1986 data, fixed

employment weights from the 1980 Census of Population are used each quarter to calculate the civilian and private indexes and the index for State and local governments. (Prior to June 1986, the employment weights are from the 1970 Census of Population.) These fixed weights, also used to derive all of the industry and occupation series indexes, ensure that changes in these indexes reflect only changes in compensation, not employment shifts among industries or occupations with different levels of wages and compensation. For the bargaining status, region, and metropolitan/nonmetropolitan area series, however, employment data by industry and occupation are not available from the census. Instead, the 1980 employment weights are reallocated within these series each quarter based on the current sample. Therefore, these indexes are not strictly comparable to those for the aggregate, industry, and occupation series.

Definitions

Total compensation costs include wages, salaries, and the employer's costs for employee benefits.

Wages and salaries consist of earnings before payroll deductions, including production bonuses, incentive earnings, commissions, and cost-of-living adjustments.

Benefits include the cost to employers for paid leave, supplemental pay (including nonproduction bonuses), insurance, retirement and savings plans, and legally required benefits (such as Social Security, workers' compensation, and unemployment insurance).

Excluded from wages and salaries and employee benefits are such items as payment-in-kind, free room and board, and tips.

Notes on the data

The Employment Cost Index for changes in wages and salaries in the private nonfarm economy was published beginning in 1975. Changes in total compensation cost—wages and salaries and benefits combined—were published beginning in 1980. The series of changes in wages and salaries and for total compensation in the State and local government sector and in the civilian nonfarm economy (excluding Federal employees) were published be-

114

ginning in 1981. Historical indexes (June 1981=100) are available on the Internet:

http://www.bls.gov/ect/

FOR ADDITIONAL INFORMATION on the Employment Cost Index, contact the Office of Compensation Levels and Trends: (202) 691–6199.

Employee Benefits Survey

Description of the series

Employee benefits data are obtained from the Employee Benefits Survey, an annual survey of the incidence and provisions of selected benefits provided by employers. The survey collects data from a sample of approximately 9,000 private sector and State and local government establishments. The data are presented as a percentage of employees who participate in a certain benefit, or as an average benefit provision (for example, the average number of paid holidays provided to employees per year). Selected data from the survey are presented in table 25 for medium and large private establishments and in table 26 for small private establishments and State and local government.

The survey covers paid leave benefits such as holidays and vacations, and personal, funeral, jury duty, military, family, and sick leave; short-term disability, long-term disability, and life insurance; medical, dental, and vision care plans; defined benefit and defined contribution plans; flexible benefits plans; reimbursement accounts; and unpaid family leave.

Also, data are tabulated on the incidence of several other benefits, such as severance pay, child-care assistance, wellness programs, and employee assistance programs.

Definitions

Employer-provided benefits are benefits that are financed either wholly or partly by the employer. They may be sponsored by a union or other third party, as long as there is some employer financing. However, some benefits that are fully paid for by the employee also are included. For example, long-term care insurance and postretirement life insurance paid entirely by the employee are included because the guarantee of insurability and availability at group premium rates are considered a benefit.

Participants are workers who are covered by a benefit, whether or not they use that benefit. If the benefit plan is financed wholly by employers and requires employees to complete a minimum length of service for eligibility, the workers are considered participants whether or not they have met the requirement. If workers are required to contribute towards the cost of a plan, they are considered participants only if they elect the plan and agree to make the required contributions.

Defined benefit pension plans use predetermined formulas to calculate a retirement benefit (if any), and obligate the employer to provide those benefits. Benefits are generally based on salary, years of service, or both.

Defined contribution plans generally specify the level of employer and employee contributions to a plan, but not the formula for determining eventual benefits. Instead, individual accounts are set up for participants, and benefits are based on amounts credited to these accounts.

Tax-deferred savings plans are a type of defined contribution plan that allow participants to contribute a portion of their salary to an employer-sponsored plan and defer income taxes until withdrawal.

Flexible benefit plans allow employees to choose among several benefits, such as life insurance, medical care, and vacation days, and among several levels of coverage within a given benefit.

Notes on the data

Surveys of employees in medium and large establishments conducted over the 1979–86 period included establishments that employed at least 50, 100, or 250 workers, depending on the industry (most service industries were excluded). The survey conducted in 1987 covered only State and local governments with 50 or more employees. The surveys conducted in 1988 and 1989 included medium and large establishments with 100 workers or more in private industries. All surveys conducted over the 1979–89 period excluded establishments in Alaska and Hawaii, as well as part-time employees.

Beginning in 1990, surveys of State and local governments and small private establishments were conducted in evennumbered years, and surveys of medium and large establishments were conducted in oddnumbered years. The small establishment survey includes all private nonfarm establishments with fewer than 100 workers, while the State and local government survey includes all governments, regardless of the number of workers. All three surveys include full- and part-time workers, and workers in all 50 States and the District of Columbia.

FOR ADDITIONAL INFORMATION on the Employee Benefits Survey, contact the Office of Compensation Levels and Trends on the Internet:

http://www.bls.gov/ebs/

Work stoppages

Description of the series

Data on work stoppages measure the number and duration of major strikes or lockouts (involving 1,000 workers or more) occurring during the month (or year), the number of workers involved, and the amount of work time lost because of stoppage. These data are presented in table 31.

Data are largely from a variety of published sources and cover only establishments directly involved in a stoppage. They do not measure the indirect or secondary effect of stoppages on other establishments whose employees are idle owing to material shortages or lack of service.

Definitions

Number of stoppages: The number of strikes and lockouts involving 1,000 workers or more and lasting a full shift or longer.

Workers involved: The number of workers directly involved in the stoppage.

Number of days idle: The aggregate number of workdays lost by workers involved in the stoppages.

Days of idleness as a percent of estimated working time: Aggregate workdays lost as a percent of the aggregate number of standard workdays in the period multiplied by total employment in the period.

Notes on the data

This series is not comparable with the one terminated in 1981 that covered strikes involving six workers or more.

FOR ADDITIONAL INFORMATION on work stoppages data, contact the Office of Compensation and Working Conditions: (202) 691–6282, or the Internet:

http:/www.bls.gov/cba/

Price Data

(Tables 2; 32-42)

PRICE DATA are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price in-

dexes are given in relation to a base period— 1982 = 100 for many Producer Price Indexes, 1982–84 = 100 for many Consumer Price Indexes (unless otherwise noted), and 1990 = 100 for International Price Indexes.

Consumer Price Indexes Description of the series

The Consumer Price Index (CPI) is a measure of the average change in the prices paid by urban consumers for a fixed market basket of goods and services. The CPI is calculated monthly for two population groups, one consisting only of urban households whose primary source of income is derived from the employment of wage earners and clerical workers, and the other consisting of all urban households. The wage earner index (CPI-W) is a continuation of the historic index that was introduced well over a half-century ago for use in wage negotiations. As new uses were developed for the CPI in recent years, the need for a broader and more representative index became apparent. The all-urban consumer index (CPI-U), introduced in 1978, is representative of the 1993-95 buying habits of about 87 percent of the noninstitutional population of the United States at that time, compared with 32 percent represented in the CPI-W. In addition to wage earners and clerical workers, the CPI-U covers professional, managerial, and technical workers, the self-employed, shortterm workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctors' and dentists' fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items are kept essentially unchanged between major revisions so that only price changes will be measured. All taxes directly associated with the purchase and use of items are included in the index.

Data collected from more than 23,000 retail establishments and 5,800 housing units in 87 urban areas across the country are used to develop the "U.S. city average." Separate estimates for 14 major urban centers are presented in table 33. The areas listed are as indicated in footnote 1 to the table. The area indexes measure only the average change in prices for each area since the base period, and do not indicate differences in the level of prices among cities.

Notes on the data

In January 1983, the Bureau changed the way in which homeownership costs are meaured for the CPI-U. A rental equivalence method replaced the asset-price approach to homeownership costs for that series. In January 1985, the same change was made in the CPI-W. The central purpose of the change was to separate shelter costs from the investment component of home-ownership so that the index would reflect only the cost of shelter services provided by owner-occupied homes. An updated CPI-U and CPI-W were introduced with release of the January 1987 and January 1998 data.

FOR ADDITIONAL INFORMATION, contact the Division of Prices and Price Indexes: (202) 691–7000.

Producer Price Indexes

Description of the series

Producer Price Indexes (PPI) measure average changes in prices received by domestic producers of commodities in all stages of processing. The sample used for calculating these indexes currently contains about 3,200 commodities and about 80,000 quotations per month, selected to represent the movement of prices of all commodities produced in the manufacturing; agriculture, forestry, and fishing; mining; and gas and electricity and public utilities sectors. The stage-of-processing structure of PPI organizes products by class of buyer and degree of fabrication (that is, finished goods, intermediate goods, and crude materials). The traditional commodity structure of PPI organizes products by similarity of end use or material composition. The industry and product structure of PPI organizes data in accordance with the Standard Industrial Classification (SIC) and the product code extension of the SIC developed by the U.S. Bureau of the Census.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

Since January 1992, price changes for the various commodities have been averaged

together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1987. The detailed data are aggregated to obtain indexes for stage-of-processing groupings, commodity groupings, durability-of-product groupings, and a number of special composite groups. All Producer Price Index data are subject to revision 4 months after original publication.

FOR ADDITIONAL INFORMATION, contact the Division of Industrial Prices and Price Indexes: (202) 691–7705.

International Price Indexes

Description of the series

The International Price Program produces monthly and quarterly export and import price indexes for nonmilitary goods and services traded between the United States and the rest of the world. The export price index provides a measure of price change for all products sold by U.S. residents to foreign buyers. ("Residents" is defined as in the national income accounts; it includes corporations, businesses, and individuals, but does not require the organizations to be U.S. owned nor the individuals to have U.S. citizenship.) The import price index provides a measure of price change for goods purchased from other countries by U.S. resi-

The product universe for both the import and export indexes includes raw materials, agricultural products, semifinished manufactures, and finished manufactures, including both capital and consumer goods. Price data for these items are collected primarily by mail questionnaire. In nearly all cases, the data are collected directly from the exporter or importer, although in a few cases, prices are obtained from other sources.

To the extent possible, the data gathered refer to prices at the U.S. border for exports and at either the foreign border or the U.S. border for imports. For nearly all products, the prices refer to transactions completed during the first week of the month. Survey respondents are asked to indicate all discounts, allowances, and rebates applicable to the reported prices, so that the price used in the calculation of the indexes is the actual price for which the product was bought or sold.

In addition to general indexes of prices for U.S. exports and imports, indexes are also

published for detailed product categories of exports and imports. These categories are defined according to the five-digit level of detail for the Bureau of Economic Analysis End-use Classification, the three-digit level for the Standard Industrial Classification (STTC), and the four-digit level of detail for the Harmonized System. Aggregate import indexes by country or region of origin are also available.

BLS publishes indexes for selected categories of internationally traded services, calculated on an international basis and on a balance-of-payments basis.

Notes on the data

The export and import price indexes are weighted indexes of the Laspeyres type. The trade weights currently used to compute both indexes relate to 2000.

Because a price index depends on the same items being priced from period to period, it is necessary to recognize when a product's specifications or terms of transaction have been modified. For this reason, the Bureau's questionnaire requests detailed descriptions of the physical and functional characteristics of the products being priced, as well as information on the number of units bought or sold, discounts, credit terms, packaging, class of buyer or seller, and so forth. When there are changes in either the specifications or terms of transaction of a product, the dollar value of each change is deleted from the total price change to obtain the "pure" change. Once this value is determined, a linking procedure is employed which allows for the continued repricing of the item.

FOR ADDITIONAL INFORMATION, contact the Division of International Prices: (202) 691–7155.

Productivity Data

(Tables 2; 43-46)

Business and major sectors

Description of the series

The productivity measures relate real output to real input. As such, they encompass a family of measures which include single-factor input measures, such as output per hour, output per unit of labor input, or output per unit of capital input, as well as measures of multifactor productivity (output per unit of combined labor and capital inputs). The Bureau indexes show the change in output rela-

tive to changes in the various inputs. The measures cover the business, nonfarm business, manufacturing, and nonfinancial corporate sectors.

Corresponding indexes of hourly compensation, unit labor costs, unit nonlabor payments, and prices are also provided.

Definitions

Output per hour of all persons (labor productivity) is the quantity of goods and services produced per hour of labor input. Output per unit of capital services (capital productivity) is the quantity of goods and services produced per unit of capital services input. Multifactor productivity is the quantity of goods and services produced per combined inputs. For private business and private nonfarm business, inputs include labor and capital units. For manufacturing, inputs include labor, capital, energy, nonenergy materials, and purchased business services.

Compensation per hour is total compensation divided by hours at work. Total compensation equals the wages and salaries of employees plus employers' contributions for social insurance and private benefit plans, plus an estimate of these payments for the self-employed (except for nonfinancial corporations in which there are no self-employed). Real compensation per hour is compensation per hour deflated by the change in the Consumer Price Index for All Urban Consumers.

Unit labor costs are the labor compensation costs expended in the production of a unit of output and are derived by dividing compensation by output. Unit nonlabor payments include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from current-dollar value of output and dividing by output.

Unit nonlabor costs contain all the components of unit nonlabor payments except unit profits.

Unit profits include corporate profits with inventory valuation and capital consumption adjustments per unit of output.

Hours of all persons are the total hours at work of payroll workers, selfemployed persons, and unpaid family

Labor inputs are hours of all persons adjusted for the effects of changes in the education and experience of the labor force.

Capital services are the flow of services from the capital stock used in production. It is developed from measures of

the net stock of physical assets—equipment, structures, land, and inventories weighted by rental prices for each type of asset.

Combined units of labor and capital inputs are derived by combining changes in labor and capital input with weights which represent each component's share of total cost. Combined units of labor, capital, energy, materials, and purchased business services are similarly derived by combining changes in each input with weights that represent each input's share of total costs. The indexes for each input and for combined units are based on changing weights which are averages of the shares in the current and preceding year (the Tornquist indexnumber formula).

Notes on the data

Business sector output is an annuallyweighted index constructed by excluding from real gross domestic product (GDP) the following outputs: general government, nonprofit institutions, paid employees of private households, and the rental value of owner-occupied dwellings. Nonfarm business also excludes farming. Private business and private nonfarm business further exclude government enterprises. The measures are supplied by the U.S. Department of Commerce's Bureau of Economic Analysis. Annual estimates of manufacturing sectoral output are produced by the Bureau of Labor Statistics. Quarterly manufacturing output indexes from the Federal Reserve Board are adjusted to these annual output measures by the BLS. Compensation data are developed from data of the Bureau of Economic Analysis and the Bureau of Labor Statistics. Hours data are developed from data of the Bureau of Labor Statistics.

The productivity and associated cost measures in tables 43–46 describe the relationship between output in real terms and the labor and capital inputs involved in its production. They show the changes from period to period in the amount of goods and services produced per unit of input.

Although these measures relate output to hours and capital services, they do not measure the contributions of labor, capital, or any other specific factor of production. Rather, they reflect the joint effect of many influences, including changes in technology; shifts in the composition of

the labor force; capital investment; level of output; changes in the utilization of capacity, energy, material, and research and development; the organization of production; managerial skill; and characteristics and efforts of the work force.

FOR ADDITIONAL INFORMATION on this productivity series, contact the Division of Productivity Research: (202) 691–5606.

Industry productivity measures

Description of the series

The BLS industry productivity indexes measure the relationship between output and inputs for selected industries and industry groups, and thus reflect trends in industry efficiency over time. Industry measures include labor productivity, multifactor productivity, compensation, and unit labor costs.

The industry measures differ in methodology and data sources from the productivity measures for the major sectors because the industry measures are developed independently of the National Income and Product Accounts framework used for the major sector measures.

Definitions

Output per hour is derived by dividing an index of industry output by an index of labor input. For most industries, output indexes are derived from data on the value of industry output adjusted for price change. For the remaining industries, output indexes are derived from data on the physical quantity of production.

The **labor input** series consist of the hours of all employees (production workers and nonproduction workers), the hours of all persons (paid employees, partners, proprietors, and unpaid family workers), or the number of employees, depending upon the industry.

Unit labor costs represent the labor compensation costs per unit of output produced, and are derived by dividing an index of labor compensation by an index of output. Labor compensation includes payroll as well as supplemental payments, including both legally required expenditures and payments for voluntary programs.

Multifactor productivity is derived by dividing an index of industry output by an index of the combined inputs consumed in producing that output. Combined inputs include capital, labor, and intermediate pur-

chases. The measure of capital input used represents the flow of services from the capital stock used in production. It is developed from measures of the net stock of physical assets—equipment, structures, land, and inventories. The measure of intermediate purchases is a combination of purchased materials, services, fuels, and electricity.

Notes on the data

The industry measures are compiled from data produced by the Bureau of Labor Statistics and the Bureau of the Census, with additional data supplied by other government agencies, trade associations, and other sources.

For most industries, the productivity indexes refer to the output per hour of all employees. For some trade and services industries, indexes of output per hour of all persons (including self-employed) are constructed. For some transportation industries, only indexes of output per employee are prepared.

FOR ADDITIONAL INFORMATION on this series, contact the Division of Industry Productivity Studies: (202) 691–5618.

International Comparisons

(Tables 47-49)

Labor force and unemployment

Description of the series

Tables 47 and 48 present comparative measures of the labor force, employment, and unemployment-approximating U.S. concepts-for the United States, Canada, Australia, Japan, and several European countries. The unemployment statistics (and, to a lesser extent, employment statistics) published by other industrial countries are not. in most cases, comparable to U.S. unemployment statistics. Therefore, the Bureau adjusts the figures for selected countries, where necessary, for all known major definitional differences. Although precise comparability may not be achieved, these adjusted figures provide a better basis for international comparisons than the figures regularly published by each country. For further information on adjustments and comparability issues, see Constance Sorrentino, "International unemployment rates: how comparable are they?" Monthly

Labor Review, June 2000, pp. 3-20.

Definitions

For the principal U.S. definitions of the labor force, employment, and unemployment, see the Notes section on Employment and Unemployment Data: Household survey data.

Notes on the data

The adjusted statistics have been adapted to the age at which compulsory schooling ends in each country, rather than to the U.S. standard of 16 years of age and older. Therefore, the adjusted statistics relate to the population aged 16 and older in France, Sweden, and the United Kingdom; 15 and older in Australia, Japan, Germany, Italy from 1993 onward, and the Netherlands; and 14 and older in Italy prior to 1993. An exception to this rule is that the Canadian statistics for 1976 onward are adjusted to cover ages 16 and older. whereas the age at which compulsory schooling ends remains at 15. The institutional population is included in the denominator of the labor force participation rates and employment-population ratios for Japan and Germany; it is excluded for the United States and the other countries.

In the U.S. labor force survey, persons on layoff who are awaiting recall to their jobs are classified as unemployed. European and Japanese layoff practices are quite different in nature from those in the United States; therefore, strict application of the U.S. definition has not been made on this point. For further information, see *Monthly Labor Review*, December 1981, pp. 8–11.

The figures for one or more recent years for France, Germany, Italy, the Netherlands, and the United Kingdom are calculated using adjustment factors based on labor force surveys for earlier years and are considered preliminary. The recent-year measures for these countries, therefore, are subject to revision whenever data from more current labor force surveys become available.

There are breaks in the data series for the United States (1990, 1994, 1997, 1998, 1999, 2000), Canada (1976) France (1992), Germany (1991), Italy (1991, 1993), the Netherlands (1988), and Sweden (1987).

For the United States, the break in series reflects a major redesign of the labor force survey questionnaire and collection methodology introduced in January 1994. Revised population estimates based on the 1990 census, adjusted for the estimated undercount, also were incorporated. In 1996, previously published data for the 1990–93 period were

revised to reflect the 1990 census-based population controls, adjusted for the undercount. In 1997, revised population controls were introduced into the household survey. Therefore, the data are not strictly conparable with prior years. In 1998, new composite estimation procedures and minor revisions in population controls were introduced into the household survey. Therefore, the data are not strictly comparable with data for 1997 and earlier years. See the Notes section on Employment and Unemployment Data of this *Review*.

BLS recently introduced a new adjusted series for Canada. Beginning with the data for 1976, Canadian data are adjusted to more closely approximate U.S. concepts. Adjustments are made to the unemployed and labor force to exclude: (1) 15-year-olds; (2) passive jobseekers (persons only reading newspaper ads as their method of job search); (3) persons waiting to start a new job who did not seek work in the past 4 weeks; and (4) persons unavailable for work due to personal or family responsibilities. An adjustment is made to include full-tine students looking for full-time work. The impact of the adjustments was to lower the annual average unemployment rate by 0.1-0.4 percentage point in the 1980s and 0.4-1.0 percentage point in

For France, the 1992 break reflects the substitution of standardized European Union Statistical Office (EUROSTAT) unemployment statistics for the unemployment data estimated according to the International Labor Office (ILO) definition and published in the Organization for Economic Cooperation and Development (OECD) annual yearbook and quarterly update. This change was made because the EUROSTAT data are more up-to-date than the OECD figures. Also, since 1992, the EUROSTAT definitions are closer to the U.S. definitions than they were in prior years. The impact of this revision was to lower the unemployment rate by 0.1 percentage point in 1992 and 1993, by 0.4 percentage point in 1994, and 0.5 percentage point in 1995.

For Germany, the data for 1991 onward refer to unified Germany. Data prior to 1991 relate to the former West Germany. The impact of including the former East Germany was to increase the unemployment rate from 4.3 to 5.6 percent in 1991.

For Italy, the 1991 break reflects a revision in the method of weighting sample data. The impact was to increase the unemployment rate by approximately 0.3 percentage point, from 6.6 to 6.9 percent in 1991.

In October 1992, the survey methodology was revised and the definition of unemployment was changed to include only those

who were actively looking for a job within the 30 days preceding the survey and who were available for work. In addition, the lower age limit for the labor force was raised from 14 to 15 years. (Prior to these changes, BLS adjusted Italy's published unemployment rate downward by excluding from the unemployed those persons who had not actively sought work in the past 30 days.) The break in the series also reflects the incorporation of the 1991 population census results. The impact of these changes was to raise Italy's adjusted unemployment rate by approximately 1.2 percentage points, from 8.3 to 9.5 percent in fourth-quarter 1992. These changes did not affect employment significantly, except in 1993. Estimates by the Italian Statistical Office indicate that employment declined by about 3 percent in 1993, rather than the nearly 4 percent indicated by the data shown in table 44. This difference is attributable mainly to the incorporation of the 1991 population benchmarks in the 1993 data. Data for earlier years have not been adjusted to incorporate the 1991 census results.

For the Netherlands, a new survey questionnaire was introduced in 1992 that allowed for a closer application of ILO guidelines. EUROSTAT has revised the Dutch series back to 1988 based on the 1992 changes. The 1988 revised unemployment rate is 7.6 percent; the previous estimate for the same year was 9.3 percent.

There have been two breaks in series in the Swedish labor force survey, in 1987 and 1993. Adjustments have been made for the 1993 break back to 1987. In 1987, a new questionnaire was introduced. Questions regarding current availability were added and the period of active workseeking was reduced from 60 days to 4 weeks. These changes lowered Sweden's 1987 unemployment rate by 0.4 percentage point, from 2.3 to 1.9 percent. In 1993, the measurement period for the labor force survey was changed to represent all 52 weeks of the year rather than one week each month and a new adjustment for population totals was introduced. The impact was to raise the unemployment rate by approximately 0.5 percentage point, from 7.6 to 8.1 percent. Statistics Sweden revised its labor force survey data for 1987-92 to take into account the break in 1993. The adjustment raised the Swedish unemployment rate by 0.2 percentage point in 1987 and gradually rose to 0.5 percentage point in 1992.

Beginning with 1987, BLS has adjusted the Swedish data to classify students who also sought work as unemployed. The impact of

this change was to increase the adjusted unemployment rate by 0.1 percentage point in 1987 and by 1.8 percentage points in 1994, when unemployment was higher. In 1998, the adjusted unemployment rate had risen from 6.5 to 8.4 percent due to the adjustment to include students.

The net effect of the 1987 and 1993 changes and the BLS adjustment for students seeking work lowered Sweden's 1987 unemployment rate from 2.3 to 2.2 percent.

Manufacturing productivity and labor costs

Description of the series

Table 49 presents comparative indexes of manufacturing labor productivity (output per hour), output, total hours, compensation per hour, and unit labor costs for the United States, Canada, Japan, and nine European countries. These measures are trend comparisons—that is, series that measure changes over time—rather than level comparisons. There are greater technical problems in comparing the levels of manufacturing output among countries.

BLS constructs the comparative indexes from three basic aggregate measures—output, total labor hours, and total compensation. The hours and compensation measures refer to all employed persons (wage and salary earners plus self-employed persons and unpaid family workers) in the United States, Canada, Japan, France, Germany, Norway, and Sweden, and to all employees (wage and salary earners) in the other countries.

Definitions

Output, in general, refers to value added in manufacturing from the national accounts of each country. However, the output series for Japan prior to 1970 is an index of industrial production, and the national accounts measures for the United Kingdom are essentially identical to their indexes of industrial production.

The 1977-97 output data for the United States are the gross product originating (value added) measures prepared by the Bureau of Economic Analysis of the U.S. Department of Commerce. Comparable manufacturing output data currently are not available prior to 1977.

U.S. gross product originating is a chain-type annual-weighted series. (For more information on the U.S. measure, see Robert E. Yuskavage, "Improved Estimates of Gross Product by Industry, 1959–94," Survey of Current Business, August 1996, pp. 133–55.) The Japanese value added series is based upon one set of fixed price weights for the years 1970 through 1997. Output series for the other foreign economies also employ fixed price weights, but the weights are updated periodically (for example, every 5 or 10 years).

To preserve the comparability of the U.S. measures with those for other economies, BLS uses gross product originating in manufacturing for the United States for these comparative measures. The gross product originating series differs from the manufacturing output series that BLS publishes in its news releases on quarterly measures of U.S. productivity and costs (and that underlies the measures that appear in tables 43 and 45 in this section). The quarterly measures are on a "sectoral output" basis, rather than a value-added basis. Sectoral output is gross output less intrasector transactions.

Total labor hours refers to hours worked in all countries. The measures are developed from statistics of manufacturing employment and average hours. The series used for France (from 1970 forward), Norway, and Sweden are official series published with the national accounts. Where official total hours series are not available, the measures are developed by BLS using employment figures published with the national accounts, or other comprehensive employment series, and estimates of annual hours worked. For Germany, BLS uses estimates of average hours worked developed by a research institute connected to the Ministry of Labor for use with the national accounts employment figures. For the other countries, BLS constructs its own estimates of average hours.

Denmark has not published estimates of average hours for 1994–97; therefore, the BLS measure of labor input for Denmark ends in 1993.

Total compensation (labor cost) includes all payments in cash or in-kind made directly to employees plus employer expenditures for legally required insurance programs and contractual and private benefit plans. The measures are from the national accounts of each country, except those for Belgium, which are developed by BLS using statistics on employment, average hours, and hourly compensation. For Canada, France, and Sweden, compensation is increased to account for other significant taxes on payroll or employment. For the United Kingdom, compensation is reduced between 1967 and 1991 to account for em-

ployment-related subsidies. Self-employed workers are included in the all-employed-persons measures by assuming that their hourly compensation is equal to the average for wage and salary employees.

Notes on the data

In general, the measures relate to total manufacturing as defined by the International Standard Industrial Classification. However, the measures for France (for all years) and Italy (beginning 1970) refer to mining and manufacturing less energy-related products, and the measures for Denmark include mining and exclude manufacturing handicrafts from 1960 to 1966.

The measures for recent years may be based on current indicators of manufacturing output (such as industrial production indexes), employment, average hours, and hourly compensation until national accounts and other statistics used for the long-term measures become available.

Occupational Injury and Illness Data

(Tables 50-51)

Survey of Occupational Injuries and Illnesses

Description of the series

The Survey of Occupational Injuries and Illnesses collects data from employers about their workers' job-related nonfatal injuries and illnesses. The information that employers provide is based on records that they maintain under the Occupational Safety and Health Act of 1970. Self-employed individuals, farms with fewer than 11 employees, employers regulated by other Federal safety and health laws, and Federal, State, and local government agencies are excluded from the survey.

The survey is a Federal-State cooperative program with an independent sample selected for each participating State. A stratified random sample with a Neyman allocation is selected to represent all private industries in the State. The survey is stratified by Standard Industrial Classification and size of employment.

Definitions

Under the Occupational Safety and Health Act, employers maintain records of nonfatal work-related injuries and illnesses that involve one or more of the following: loss of consciousness, restriction of work or motion, transfer to another job, or medical treatment other than first aid.

Occupational injury is any injury such as a cut, fracture, sprain, or amputation that results from a work-related event or a single, instantaneous exposure in the work environment.

Occupational illness is an abnormal condition or disorder, other than one resulting from an occupational injury, caused by exposure to factors associated with employment. It includes acute and chronic illnesses or disease which may be caused by inhalation, absorption, ingestion, or direct contact.

Lost workday injuries and illnesses are cases that involve days away from work, or days of restricted work activity, or both.

Lost workdays include the number of workdays (consecutive or not) on which the employee was either away from work or at work in some restricted capacity, or both, because of an occupational injury or illness. BLS measures of the number and incidence rate of lost workdays were discontinued beginning with the 1993 survey. The number of days away from work or days of restricted work activity does not include the day of injury or onset of illness or any days on which the employee would not have worked, such as a Federal holiday, even though able to work.

Incidence rates are computed as the number of injuries and/or illnesses or lost work days per 100 full-time workers.

Notes on the data

The definitions of occupational injuries and illnesses are from *Recordkeeping Guidelines* for Occupational Injuries and Illnesses (U.S. Department of Labor, Bureau of Labor Statistics, September 1986).

Estimates are made for industries and employment size classes for total recordable cases, lost workday cases, days away from work cases, and nonfatal cases without lost workdays. These data also are shown separately for injuries. Illness data are available for seven categories: occupational skin diseases or disorders, dust diseases of the lungs, respiratory conditions due to toxic agents, poisoning (systemic effects of toxic agents), disorders due to physical agents (other than toxic materials), disorders associated with repeated trauma, and all other occupational illnesses.

The survey continues to measure the num-

ber of new work-related illness cases which are recognized, diagnosed, and reported during the year. Some conditions, for example, long-term latent illnesses caused by exposure to carcinogens, often are difficult to relate to the work-place and are not adequately recognized and reported. These long-term latent illnesses are believed to be understated in the survey's illness measure. In contrast, the overwhelming majority of the reported new illnesses are those which are easier to directly relate to workplace activity (for example, contact dermatitis and carpal tunnel syndrome).

Most of the estimates are in the form of incidence rates, defined as the number of injuries and illnesses per 100 equivalent full-time workers. For this purpose, 200,000 employee hours represent 100 employee years (2,000 hours per employee). Full detail on the available measures is presented in the annual bulletin, Occupational Injuries and Illnesses: Counts, Rates, and Characteristics.

Comparable data for more than 40 States and territories are available from the BLS Office of Safety, Health and Working Conditions. Many of these States publish data on State and local government employees in addition to private industry data.

Mining and railroad data are furnished to BLS by the Mine Safety and Health Administration and the Federal Railroad Administration. Data from these organizations are included in both the national and State data published annually.

With the 1992 survey, BLS began publishing details on serious, nonfatal incidents resulting in days away from work. Included are some major characteristics of the injured and ill workers, such as occupation, age, gender, race, and length of service, as well as the

circumstances of their injuries and illnesses (nature of the disabling condition, part of body affected, event and exposure, and the source directly producing the condition). In general, these data are available nationwide for detailed industries and for individual States at more aggregated industry levels.

http://www.bls.gov/iif/

Census of Fatal Occupational Injuries

The Census of Fatal Occupational Injuries compiles a complete roster of fatal job-related injuries, including detailed data about the fatally injured workers and the fatal events. The program collects and cross checks fatality information from multiple sources, including death certificates, State and Federal workers' compensation reports, Occupational Safety and Health Administration and Mine Safety and Health Administration records, medical examiner and autopsy reports, media accounts, State motor vehicle fatality records, and follow-up questionnaires to employers.

In addition to private wage and salary workers, the self-employed, family members, and Federal, State, and local government workers are covered by the program. To be included in the fatality census, the decedent must have been employed (that is working for pay, compensation, or profit) at the time of the event, engaged in a legal work activity, or present at the site of the incident as a requirement of his or her job.

Definition

A fatal work injury is any intentional or unintentional wound or damage to the body resulting in death from acute exposure to energy, such as heat or electricity, or kinetic energy from a crash, or from the absence of such essentials as heat or oxygen caused by a specific event or incident or series of events within a single workday or shift. Fatalities that occur during a person's commute to or from work are excluded from the census, as well as work-related illnesses, which can be difficult to identify due to long latency periods.

Notes on the data

Twenty-eight data elements are collected, coded, and tabulated in the fatality program, including information about the fatally injured worker, the fatal incident, and the machinery or equipment involved. Summary worker demographic data and event characteristics are included in a national news release that is available about 8 months after the end of the reference year. The Census of Fatal Occupational Injuries was initiated in 1992 as a joint Federal-State effort. Most States issue summary information at the time of the national news release.

FOR ADDITIONAL INFORMATION on the Census of Fatal Occupational Injuries contact the BLS Office of Safety, Health, and Working Conditions at (202) 691–6175, or the Internet at:

http://www.bls.gov/iif/

¹ The population figures are not seasonally adjusted.

NOTE: Estimates for the above race groups (white and black or African American) do not sum to totals because data are not presented for all races. In addition, persons whose ethnicity is identified as Hispanic or Latino may be of any race and, therefore, are classified by ethnicity as well as by race. Beginning in January 2003, data reflect revised population controls used in the household survey.

Data relate to production workers in natural resources and mining and manufacturing, construction workers in construction, and nonsupervisory workers in the service-providing industries.

NOTE: Data reflect the conversion to the 2002 version of the North American Industry Classification System (NAICS), replacing the Standard Industrial Classification (SIC) system. NAICS-based data by industry are not comparable with SIC-based data. See "Notes on the data" for a description of the most recent benchmark revision.

16. Average weekly earnings of production or nonsupervisory workers¹ on private nonfarm payrolls, by industry

| Industry | Annual a | average | 2002 | | | | | | 20 | 03 | | | | | |

Data relate to production workers in natural resources and mining and manufacturing, construction workers in construction, and nonsupervisory workers in the service-providing industries.

NOTE: Data reflect the conversion to the 2002 version of the North American

Industry Classification System (NAICS), replacing the Standard Industrial Classifification (sic) system. NAICS-based data by industry are not comparable with sic-based data. See "Notes on the data" for a description of the most recent benchmark revision.

Dash indicates data not available. p = preliminary.

¹ Includes areas not officially designated as counties. See Notes on Current Labor Statistics.

Note: Data pertain to workers covered by Unemployment Insurance (UI) and Unemployment Compensation for Federal Employees (UCFE) programs. The 248 U.S. counties comprise 66.2 percent of the total covered workers in the United States.

² Percent changes were computed from annual employment and pay data adjusted for noneconomic county reclassifications. See Notes on Current Labor Statistics.

³ Rankings for percent change in employment are based on the 249 counties that are comparable over the year.

⁴ Totals for the United States do not include data for Puerto Rico.

Current Labor Statistics: Labor Force Data

^{&#}x27; Consists of private industry workers (excluding farm and household workers) and State and local government (excluding Federal Government) workers.

State and local government (excluding Federal Government) workers.

² Consists of legislative, judicial, administrative, and regulatory activities.

This series has the same industry and occupational coverage as the Hourly Earnings index, which was discontinued in January 1989.

⁴ Includes, for example, library, social, and health services.

27. Employment Cost Index, benefits, private industry workers by occupation and industry group

| Reimbursement accounts 2 | | | | | | | | | | |

The definitions for paid sick leave and short-term disability (previously sickness and fits at less than full pay. accident insurance) were changed for the 1995 survey. Paid sick leave now includes only 2 Prior to 1995, reimbursement accounts included premium conversion plans, which plans that specify either a maximum number of days per year or unlimited days. Shortterms disability now includes all insured, self-insured, and State-mandated plans available on a per-disability basis, as well as the unfunded per-disability plans previously reported as sick leave. Sickness and accident insurance, reported in years prior to this survey, included only insured, self-insured, and State-mandated plans providing per-disability bene-

Agricultural and government employees are included in the total employed and total working time; private household, forestry, and fishery employees are excluded. An explanation of the measurement of idleness as a percentage of the total time worked is found in "Total economy measures of strike idleness,"

Monthly Labor Review, October 1968, pp.54-56.

¹ Foods, fuels, and several other items priced every month in all areas; most other goods and services priced as indicated:

Report: Anchorage, AK; Cincinnatti, OH-KY-IN; Kansas City, MO-KS; Milwaukee-Racine, WI; Minneapolis-St. Paul, MN-WI; Pittsburgh, PA; Port-land-Salem, OR-WA; St Louis, MO-IL; San Diego, CA; Tampa-St. Petersburg-Clearwater, FL.

NOTE: Local area CPI indexes are byproducts of the national CPI program. Each local index has a smaller sample size and is, therefore, subject to substantially more sampling and other measurement error. As a result, local area indexes show greater volatility than the national index, although their long-term trends are similar. Therefore, the Bureau of Labor Statistics strongly urges users to consider adopting the national average CPI for use in their escalator clauses. Index applies to a month as a whole, not to any specific date.

Dash indicates data not available.

M-Every month.

¹⁻January, March, May, July, September, and November.

²⁻February, April, June, August, October, and December.

² Regions defined as the four Census regions.

³ Indexes on a December 1996 = 100 base.

⁴ The "North Central" region has been renamed the "Midwest" region by the Census Bureau. It is composed of the same geographic entities.

⁵ Indexes on a December 1986 = 100 base.

⁶ In addition, the following metropolitan areas are published semiannually and appear in tables 34 and 39 of the January and July issues of the CPI Detailed

⁷ Indexes on a November 1996 = 100 base.

34. Annual data: Consumer Price Index, U.S. city average, all items and major groups

[1982-84 = 100]

¹ Data for 1989 and subsequent years are based on the *Standard Industrial Class-ification Manual*, 1987 Edition. For this reason, they are not stricily comparable with data for the years 1985–88, which were based on the *Standard Industrial Classification Manual*, 1972 Edition, 1977 Supplement.

NOTE: Dash indicates data not available.

² Beginning with the 1992 survey, the annual survey measures only nonfatal injuries and illnesses, while past surveys covered both fatal and nonfatal incidents. To better address fatalities, a basic element of workplace safety, BLS implemented the Census of Fatal Occupational Injuries.

³ The incidence rates represent the number of injuries and illnesses or lost workdays per 100 full-time workers and were calculated as (N/EH) X 200,000, where:

N = number of injuries and illnesses or lost workdays;

EH = total hours worked by all employees during the calendar year; and 200,000 = base for 100 full-time equivalent workers (working 40 hours per week, 50 weeks per year).

⁴ Beginning with the 1993 survey, lost workday estimates will not be generated. As of 1992, BLS began generating percent distributions and the median number of days away from work by industry and for groups of workers sustaining similar work disabilities.

⁵ Excludes farms with fewer than 11 employees since 1976.

51. Fatal occupational injuries by event or exposure, 1997-2002

| | Fatalities | | | | | | |
|---|------------|-------------------|--------|---------|--|--|--|
