

U.S. Department of Labor
Hilda L. Solis, Secretary

U.S. Bureau of Labor Statistics
John M. Galvin, Acting Commissioner

The *Monthly Labor Review* is published monthly by the Bureau of Labor Statistics of the U.S. Department of Labor. The *Review* welcomes articles on employment and unemployment, compensation and working conditions, the labor force, labor-management relations, productivity and technology, occupational safety and health, demographic trends, and other economic developments.

The *Review's* audience includes economists, statisticians, labor relations practitioners (lawyers, arbitrators, etc.), sociologists, and other professionals concerned with labor-related issues. Because the *Review* presents topics in labor economics in less forbidding formats than some social science journals, its audience also includes laypersons who are interested in the topics, but are not professionally trained economists, statisticians, and so forth.

In writing articles for the *Review*, authors should aim at the generalists in the audience on the assumption that the specialist will understand. Authors should use the simplest exposition of the subject consonant with accuracy and adherence to scientific methods of data collection, analysis, and drawings of conclusions. Papers should be factual and analytical, not polemical in tone. Potential articles, as well as communications on editorial matters, should be submitted to:

Women's employment, education, and the gender gap in 17 countries

Data from the Luxembourg Income Study show that, among married or cohabiting mothers, better educated women are more likely to be employed; gender inequality in annual earnings is thus less extreme among the well educated than among those with less education, driven largely by educated women's higher employment

Paula England,
Janet Gornick,
and
Emily Fitzgibbons
Shafer

One commonsense view of women's employment is that working-class women have always been more likely to work for pay than other women because of their families' need for their paycheck. But in fact, recent evidence shows higher levels of employment for highly educated women than for the less educated, despite the fact that well-educated women typically have higher earning husbands. This article uses data from a number of high- and middle-income countries to investigate how women's employment and hours worked, and the gender gap in annual and hourly earnings, vary by educational level. Focusing on commonalities across countries, the analyses presented are limited to adults 25 to 54 years of age who have a marital or cohabiting partner of the other gender and, for some considerations, to the subset of these adults who have children in the household. The countries examined are Austria, Brazil, Canada, the Czech Republic, Estonia, Germany, Greece, Guatemala, Ireland, Israel, Luxembourg, Mexico, the Netherlands, Spain, the United Kingdom (U.K.), the United States (U.S.), and Uruguay.¹

Education and women's employment

Recent research on both the United States and a number of European countries shows that women's employment is higher at higher educational levels.² In the United States,

the pattern of well-educated women having higher employment than less educated women dates back to at least 1950.³ Moreover, the positive effect of women's own education on their employment has increased steadily, while the negative effect of their husbands' earnings has declined.⁴ A similar decline over time in the impact of husbands' earnings on wives' employment occurred in Sweden.⁵ What is lacking, however, is an examination of whether the pattern of more educated women having higher employment levels holds across a large range of affluent countries.

What do theories tell us about whether more educated or less educated women would be expected to be employed at higher rates and about the effect of their husbands' earnings on women's employment? Economic theory offers two competing principles: income and price effects. Price effects are also called price-of-time effects or opportunity-cost effects. Women with more education have higher earning power; thus, the dollar value of what they would forego by staying home with a child is greater for them. On the basis of these higher opportunity costs, well-educated women are expected to have higher employment.⁶ By contrast, the "income effect" refers to the fact that the more sources of income individuals have other than their own earnings, the less they will work for pay.⁷ Income in the form of a spouse's earnings can be used to "buy" lei-

Paula England is a professor of sociology at New York University, Janet Gornick is a professor of political science and sociology at the Graduate Center of the City University of New York and director of the Luxembourg Income Study, and Emily Fitzgibbons Shafer is a Robert Wood Johnson Health and Society Scholar at Harvard University. sure or homemaking time. Given marital homogamy—the tendency to marry persons of similar education and earning power⁸—these two effects operate at cross-purposes on any given woman. The highly educated woman typically has the higher earning husband, so her own education encourages her employment while his earnings discourage it. The less educated woman typically has the lower earning husband, so her own education discourages her employment while his low earnings increase her need to be employed. Thus, it is an empirical question which of the two effects predominates. When people say that working-class or poor women work for pay because their families need the money, they are saying, in lay language, that the income effect predominates over the opportunity-cost effect. Past research showing that better educated women are more likely to be employed is consistent with the opportunity-cost effect predominating.

Sociologists focus at least in part on nonmonetary motivations for employment, such as whether one can get an interesting, meaningful, or identity-enhancing job.⁹ The strong cultural construction of motherhood as the responsibility of, and source of meaning for, women requires that paid work be meaningful in order to compete for women's focus.¹⁰ If the only jobs one can get are demeaning, full-time child rearing may seem a more meaningful option if it can be afforded even minimally. This reasoning, too, would suggest that more highly educated women, who have access to more interesting and fulfilling jobs, have higher employment levels. Such reasoning is consistent with a broader opportunity-cost argument than is typically used by economists. In this broader view, what is foregone by staying home with children includes not only wages, but also identity and the satisfaction of having interesting, meaningful work.¹¹ In addition, sociologists have pointed out that education inculcates gender-egalitarian attitudes; thus, highly educated women are expected to have higher employment levels for this ideological reason as well.¹²

Another factor affecting which women are employed is the cost of childcare. If mothers, rather than fathers, are the ones responsible for care, then the benefits of a woman's job have to outweigh her childcare costs in order for it to make economic sense that she take the job. Given this cost-benefit analysis, highly educated women are more likely to be employed than less educated women because they can earn more, net of childcare costs. Note, however, that childcare costs cannot be the only factor affecting women's employment: if it were, we would not expect an educational gradient on employment in countries that provide large subsidies for childcare.

Education and the gender earnings gap

If nonearners are included in the analyses that follow (let their earnings be 0), then any group that has higher women's employment would be expected to have greater gender equality in annual earnings. But what about hourly earnings (i.e., wages)? On the one hand, past research shows that some, though surely not all, of the gender gap in wages flows from women's employment interruptions,¹³ so if more educated women are employed more continuously relative to men, then the gender gap in wages among the employed should be less at high educational levels. On the other hand, demand-side gender discrimination against women as a whole or against mothers may be greater at higher educational levels, as is suggested by "glass ceiling" arguments. Moreover, the extra-hours demands of jobs at the top are more difficult to reconcile with mothering. Together, these two factors suggest a larger gender gap in wages or annual earnings at higher educational levels.

To date, the empirical literature has addressed the issue of education and the gender earnings gap only indirectly, by examining gender differences in rates of return to education. If the percentage by which wages go up for each increment of education is higher for men than women, then the gender pay gap at higher educational levels must be larger in percentage terms. By contrast, if rates of return to education are higher for women, then the gender gap in pay would be smaller at higher educational levels. The evidence is mixed in Europe, but most U.S. studies find that women receive a higher percent return for each year of education.¹⁴ Of course, higher returns to education for women than for men do not imply that women earn higher wages than men at high education levels: when women's returns are higher, generally the finding is that men earn more than women at every educational level but the gap is smaller at higher educational levels.

Data and methods

The data that follow are from the Luxembourg Income Study (LIS), a compilation of microdata—primarily national probability samples of households—from 45 countries. LIS data are unique in that a team collects and harmonizes datasets from the various countries in order to facilitate cross-national research.¹⁵ Each dataset provides household- and individual-level data and is rich in demographic, employment, and income information. The LIS datasets vary with regard to the definition of "employment": some define "employment" as "having any paid activity" (even if only 1 hour during the reference

period), whereas others define “employment” on the basis of whether it is the respondent’s main activity (so that a woman who says that her main activity is homemaking, but who works for pay several hours a week, would not be said to have employment). LIS datasets also differ as to whether the reference period is the present, as opposed to a longer reference period, such as the previous year. Rates of employment will be higher when what is measured is employment in the previous year versus current employment, particularly for women. Thus, to maximize cross-national comparability, the subsequent analyses are limited to 17 high- and middle-income countries for which there are data on whether persons are currently employed (i.e., the reference period is the present), according to the standard of having *any paid* activity (rather than employment being the *main* activity). This measure is then used to define “employment.” (Thus, persons classified as “not employed” include both the unemployed and those not in the labor force.) The analyses use the most recent LIS data available: data from 2004 and 2006 for the 17 countries examined. Individual adults are the units of analysis, and all results are weighted to be representative of the given country’s population.

The aim of the analyses to be presented is to examine educational differences (or their absence) in women’s employment rates, women’s and men’s hours worked per week, and gender inequality in both annual and hourly earnings. The sample comprises adults between the ages of 25 and 54 who are married or cohabiting. That age range was chosen because by 25 most individuals have finished schooling and by 54 few individuals have retired. The analyses are limited to married and cohabiting men and women (hereafter, often “husbands and wives,” for brevity) because of the article’s focus on women’s employment and because it is largely among women with partners that there is some tradition of opting out of employment. Of course, opting out of employment is most common when women have young children. Thus, when descriptive statistics are presented, for each educational level, on the percentage of women who are employed, and on their hours worked, the sample is further delimited to only married or cohabiting parents who have at least one child younger than 7 in the household. This type of arrangement is most likely to have a breadwinner and a homemaker. Note, however, that the descriptive statistics examining the gender gap in annual and hourly earnings include all married and cohabiting individuals, because sample sizes for partnered individuals with a child under 7 and with hourly earnings are small in the lowest educational group in some countries. Similarly, the subsequent logistic regression analysis predict-

ing women’s employment uses all married and cohabiting women, but includes the age of the youngest child as a control variable in assessing the effects of education and the male partner’s earnings on women’s employment.¹⁶

Because, as just mentioned, the analyses that follow are limited to men and women with a marital or cohabiting partner of the other gender, the partners had to be identified in the data. Thus, household heads (with partners of the other gender) and the partners of heads were selected. This construction leaves some imprecision, failing to capture a small number of partners: adults who live with partners, but who are neither the head, nor the partner of the head, of their household (e.g., a married couple living with one of their parents who is the head of the household). In addition, as discussed earlier, some of the analyses to be presented are further limited to parents with a child under 7 in the household. The subsample for these analyses might include some partnered nonparents mistakenly identified as parents: household heads with partners, or partners of heads, living with children who are neither their nor their partner’s children. However, in the vast majority of cases, it seems safe to assume that the persons identified as parents are either parents or stepparents. Of course, a number of male stepparents are undoubtedly in the sample, because women tend to retain coresidence with their children from previous relationships.

A number of the descriptive statistics to be presented focus on proportions or central tendencies for individuals of various educational levels. For each country examined, the percentage of women employed at each level of their own education is shown, as is the percentage of women employed at each level of their male partners’ education. For those who are employed, the average number of hours usually worked per week is shown, by education, separately for women and men. How gender inequality in earnings varies by education is demonstrated in two ways. First, the ratio of women’s to men’s average annual earnings is computed, with those not employed for the entire year assigned the value 0. Second, to examine earnings inequality among just those who are currently employed, the ratio of women’s to men’s average hours-adjusted earnings—annual earnings divided by 48 (the typical number of weeks worked per year) and then divided by usual hours worked currently per week—is displayed. The latter is the closest number to an hourly wage rate obtainable from the LIS data; its limitation is that it captures differences in hourly earnings only to the extent that all workers worked the same number of weeks the previous year. To avoid thorny issues of how to render the currencies of various countries comparable (e.g., deciding between exchange rates

and purchasing parity), average annual earnings or wages are shown simply as ratios of women's to men's earnings or wages in some currency, not as separate amounts for men and women. The presentation of ratios goes directly to the article's concern with gender equality. These two types of male–female ratios—the ratio of women's to men's average annual earnings and the ratio of women's to men's average hours-adjusted earnings—are shown for each education level.

The descriptive analyses reveal higher women's employment with more education, but these are only bivariate relationships. Accordingly, logistic regression analyses are carried out to assess effects of women's education and their male partners' earnings on the women's employment, controlling for other variables. The earnings of male partners are divided into seven ordered categories, with all male partners given a score for the percentile into which their earnings fall within the distribution of the earnings of other male partners in their country's sample. Then the part of the 0–20th percentile made up of men with no earnings is separated out as one distinct category, followed by the remaining men in the 0–20th percentile, those in the 20th–39th percentile, the 40th–59th percentile (the reference category in the

logistic regression), the 60th–79th percentile, the 80th–94th percentile, and, to capture the very top earners in each country, the 95th–100th percentile.

Educational attainment is measured as low, medium, or high on the basis of one of the standardized variables provided by LIS; persons of low educational attainment are those who have not completed upper secondary education (an international designation that corresponds roughly to what in the United States would be called high school), persons of medium educational attainment are those who have completed upper secondary education and/or some form of nonspecialized vocational education, and persons of high educational attainment are those who have completed any specialized vocational or postsecondary education, or more.¹⁷

Results: education and employment

Chart 1 shows, for each country and each of the three education groups examined, the percentage of partnered women with a child under 7 who are employed. In all the countries but one (the Czech Republic), the group of partnered mothers with high education has the highest percent employed, and in all but two countries (Canada and

Chart 1. Proportion employed among cohabiting or married 25- to 54-year-old women with a child younger than 7, by their own and their partners' education

SOURCE: Luxembourg Income Study.

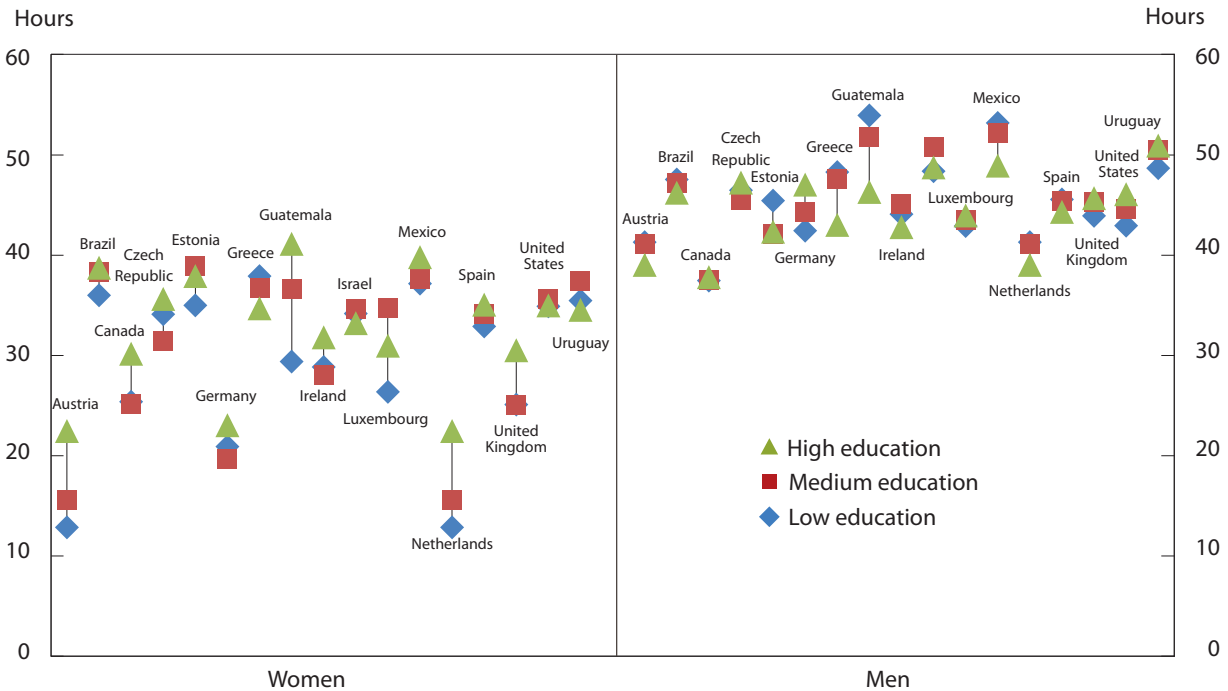

Luxembourg) those with the lowest education have the lowest percent employed (in the two exceptions, women with low and medium education do not differ much in employment). Arranging these mothers of young children by their husband's (or cohabiting partner's) education reveals a similar pattern: women are more likely to be employed if their partners have more education. This pattern is striking because male partners with more education generally have higher incomes; nonetheless, female partners of men with higher education are not any less likely to be employed, probably because of the strong correlation between the man's education and that of his female partner. (These results are, of course, limited to partnered women with a child under 7, but the same positive relationship between education and employment holds for all partnered women.) In sum, more educated women are more likely to be employed.

What about hours worked in the market for those who are employed? Clearly, from chart 1, well-educated women are more likely to be employed, but among the employed, do they work more hours per week? As chart 2 indicates, hours worked among the employed vary little by education for women or men, and the direction of whatever differences there are varies by country.¹⁸ (The same absence of relationship between education and hours worked holds

if the sample includes all men and women partnered to a member of the other gender, rather than just parents of young children.) One possible explanation for why more educated women would be employed at higher rates, but not work more hours if employed, is that people generally have more control over whether or not they are employed than they do over their hours. In some countries, there is limited demand for part-time or other reduced-hours work and almost none in more remunerative sectors.

Table 1 presents results obtained from regression analyses examining education–employment linkages while controlling for women's male partner's annual earnings, presence of children, and age of youngest child. As expected, the presence of young children deters women's employment.¹⁹ The analyses show that, in every country, women in the medium education category are more likely than those in the lowest category to be employed. The odds ratios range from 1.24 in Luxembourg, indicating that a woman with a medium level of education has a 24-percent-higher likelihood of employment than a woman with low education, to 3.69 in Guatemala, indicating that the former is more than 3 times as likely to be employed as the latter. More dramatically, in every country, the most educated women are most likely to be employed, with the smallest odds ratio (for this group's

¹ All entries are statistically significant at $p < .001$, except where otherwise indicated. ⁴ Statistically significant at $p < .01$.

² Not statistically significant. ⁵ Because of the low male employment-to-population ratio in Israel, men in the 0–20th percentile of earnings all have zero earnings and are captured in the zero-earnings category.

³ Percentiles of the distribution of annual earnings among the male cohabiting or married partners of the women in the analyses. SOURCE: Luxembourg Income Study.

odds relative to the odds of those with low education) being Estonia's 2.40 and seven countries having odds ratios greater than 6. In other words, in all countries women in the high education category are more than 2 times as likely to be employed as women in the lowest education category, and in some countries they are more than 6 times as likely.

Net of other variables, are women with male partners more likely to be homemakers (or not employed for

other reasons) if their male partners earn more relative to other male partners in their country? The logistic regressions in table 1 show that the effect of male partners' earnings is *nonmonotonic*, changing direction across the range of men's earnings. (All of the odds ratios presented show effects of being in the category in question relative to having a husband whose earnings are in the middle of the distribution: between the 40th and 59th percentile of

married or cohabiting men's earnings for the country.) In 12 out of the 17 countries examined (the exceptions being Greece, Luxembourg, Mexico, the United States, and Uruguay), women are less likely to be employed if their husband was not employed all year (and thus had earnings of 0). Odds ratios for these 12 countries with negative effects range from .16 to .82, indicating that women's odds of employment if their partners had no earnings during the previous year are between 16 percent and 82 percent of what the odds are (or, equivalently, between 84 percent and 18 percent less) for women with partners in the middle income category.

These findings for couples with men at the bottom of the income distribution are counterintuitive and not predicted by any theory. It would seem more plausible that, in households where the man has no or extremely low earnings, the woman would feel more of a need to seek employment, but these women actually have unusually low employment rates. Possibly, this finding results from the effects of some unmeasured variables on which partners are similar. For example, geographically specific recessions will create pockets where both spouses are unemployed. Or it may be that persons who are unable to work because of disability may disproportionately cohabit with or marry each other, sometimes producing two nonemployed persons supported by means-tested income maintenance programs or extended family assistance.

The group of countries examined is split about half and half as to whether the men in the bottom 20th percentile of earnings—but who have some earnings—have female partners with lower or higher employment than do men in the middle of the earnings distribution. Above the middle, the findings are largely what would be expected from the income effect: in most countries, the higher men's incomes above the middle of the distribution, the less likely their female partners are to be employed (controlling for women's own education). The only exception is Israel, where women with male partners earning in the top three categories (above the 94th, from the 80th to the 94th, and from the 60th to the 79th percentiles) are more likely to be employed than women whose partners are in the middle of the male earnings distribution. In sum, women are less likely to be employed as their partner's earnings go up, but with two large exceptions: women whose partners have no (or, in about half the countries, extremely low) earnings and women with high-earning partners in Israel.

Results: education and the earnings gap

Chart 3 shows the ratio of women's to men's annual earnings, with those without earnings assigned 0 in the averages, for all partnered individuals. With three exceptions (the Czech Republic, the United States, and Uruguay), women's median annual earnings relative to men's are higher for the higher education groups. However, chart 4 makes it clear that this educational differential comes mostly from highly educated women being more likely to be employed relative to men at the same level of education, not from a lower gender hourly earnings gap among those with high education. To approximate a wage rate, annual earnings are divided by 48 weeks and then divided by usual hours currently worked per week, limiting the analysis at this point to the employed.²⁰ Chart 4 shows the ratio of women's to men's hours-adjusted earnings for the employed. There is no clear pattern: out of 17 countries, in 8 the ratio of partnered women's to men's wages is highest among the highly educated group, but in 7 countries (Austria, Brazil, Germany, Mexico, the Netherlands, the United States, and Uruguay) this female-to-male ratio is lowest for the highly educated. Moreover, in many countries, including the United States, the gap does not differ much by education. So, why does the more continuous employment of highly educated women not translate into hourly earnings that are higher relative to those of men in the same education group, given past findings²¹ showing that employment experience is an important component of the gender pay gap? One possibility is that there is a counteracting factor such that the right-hand tail of the earnings distribution is more extreme among men than among women. Or, in more familiar language, highly educated women are the ones most likely to encounter the glass ceiling.

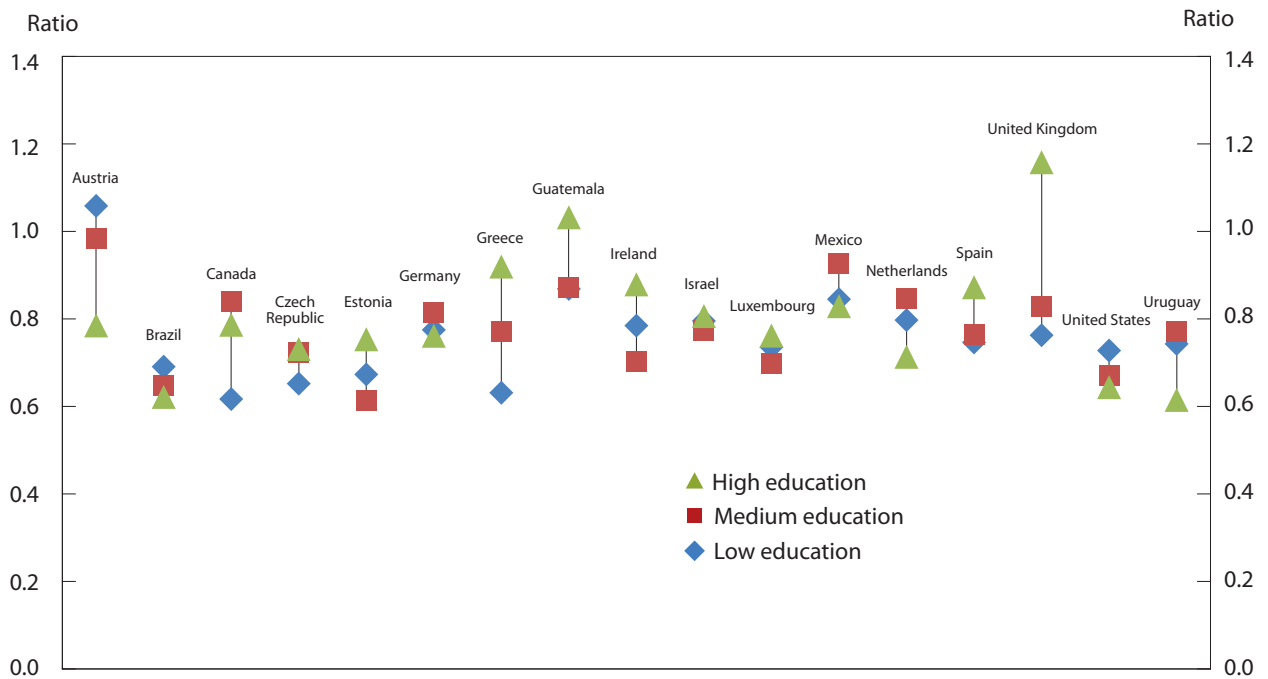

IN EACH OF THE 17 HIGH- AND MIDDLE-INCOME countries examined in this article, women with more education are more likely to be employed than women with less education. Effects of men's earnings on the employment of their female partners vary by country and are not consistently negative across the range of men's earnings. Although gender inequality in wage rates varies little by education, when those who are not employed are included in the analysis, gender inequality in annual earnings is seen to be smaller among those with higher education, largely because more of the women with high education are employed. □

Notes

¹ The article studies “high” and “middle” income countries, as indicated by the World Bank classification system, which is based on per capita gross national income. At the time the datasets were constructed, 13 of the 17 countries examined were considered high-income countries and 4—Brazil, Guatemala, Mexico, and Uruguay—were classified as middle-income countries. In what follows, the term “affluent” encompasses both high- and middle-income (as opposed to low-income) countries.

¹¹ Although economists generally ignore nonpecuniary features of jobs when discussing opportunity costs, their theory of “compensating differentials” also entails a claim that jobs are chosen for both pecuniary and nonpecuniary reasons. (On compensating differentials, see,

e.g., Paula England, *Comparable Worth: Theories and Evidence* (New York, Aldine de Gruyter, 1992), chapter 2.)

¹² Often, studies measure egalitarian gender ideology in part by how favorable respondents are to the—once controversial—notion that women’s having employment is appropriate. The idea is that a favorable attitude indicates a rejection of the traditional notion that only men should be breadwinners and only women should be homemakers. (See Karin L. Brewster and Irene Padavic, “Change in Gender-Ideology, 1977–1996: The Contributions of Intracohort Change and Population Turnover,” *Journal of Marriage and the Family*, May 2000, pp. 477–487; Pi-Ling Fan and Margaret Mooney Marini, “Influences on Gender-Role Attitudes during the Transition to Adulthood,” *Social Science Research*, June 2000, pp. 258–283; Matthijs Kalmijn and Gerbert Kraaykamp, “Social Stratification and Attitudes: A Comparative Analysis of the Effects of Class and Education in Europe,” *British Journal of Sociology*, December 2007, pp. 547–576; and Knud Knudsen and Kari Waerness, “National Context, Individual Characteristics and Attitudes on Mothers’ Employment: A Comparative Analysis of Great Britain, Sweden and Norway,” *Acta Sociologica*, January 2001, pp. 67–79.)

¹⁵ See “Assessing Income Inequality, Measuring Poverty, Comparing Employment Outcomes, Analysing Assets & Debt, Researching Policy Impacts” (Luxembourg City, Luxembourg, Cross-National Data Center, 2010–2012), <http://www.lisproject.org>.

¹⁶ All the descriptive and regression analyses undertaken in this article exclude individuals who are in the military, those engaged in agriculture, and the self-employed; the reason is that in these groups there is substantial “noise” in reports of hours worked.

¹⁷ The educational attainment recode provided by LIS is based on the International Standard Classification of Education, known as ISCED97. One challenge that comparative researchers often grapple with is the placement of vocational education programs, because the distinction between nonspecialized and specialized vocational education is not always straightforward and because many surveys do not distinguish between the two. In fact, the U.S. survey that is the source of the U.S. data in LIS, the Current Population Survey (CPS), is an example of the latter. The 2004 CPS has only one category that refers to vocational education, and it is labeled “associate degree, occupational.” In accordance with the ISCED97 guidelines, the category is classified as “high” in the LIS recode. In other countries’ surveys, there are vocational education categories that correspond to “basic” or “secondary” vocational education; ISCED97 would code these categories as “medium” educational attainment.

¹⁸ One striking finding that emerges from chart 2 is that married or cohabiting men with children report exceedingly long weekly hours in most of the countries examined. Nearly everywhere, these fathers’ mean weekly hours are well above 40 per week and, in some cases, above 50 per week. This level of worktime exceeds the normal workweek in most of these countries, suggesting that fathers often work overtime and/or hold multiple jobs. Such a finding indicates

Women's Employment Earnings

that the widespread gaps in work hours between employed men and women are shaped both by mothers' short hours (their mean hours are mostly below 40 per week) and by fathers' long hours (usually 40 and above). That said, as noted earlier, there is a weak relationship between employed persons' hours and their educational attainment, so men's remarkably long workweeks contribute to the gender gap in hours across the educational spectrum.

¹⁹ For an examination of how the relationship between children and women's employment has changed differentially between single and married women in recent years in the United States, see Saul D. Hoffman, "The changing impact of marriage and children on women's labor force participation," *Monthly Labor Review*, February 2009, pp. 3–14, <http://www.bls.gov/opub/mlr/2009/02/art1full.pdf>.

²⁰ Although the LIS data include the number of weeks worked in

the previous year for some countries, that variable is not available for all of the countries examined. Thus, in reporting gender gaps in wage, it is assumed that women and men worked the same number of weeks that year—an assumption that is understood to be problematic. In many countries, workers have the option to take off substantial time for vacation and family leave. In most cases, these days or weeks are paid (by social insurance), so the fact that women and men utilize the programs involved at different rates is likely to introduce limited bias into the results obtained. Of more concern is that, on average, women are employed fewer weeks per year, in part because women are more likely than men to have just entered employment. Thus, the gender differential in wages is undoubtedly overstated, more in some countries than in others. The situation is mitigated somewhat by the absence of a clear relationship between education and the gender gap in wages.

Employment projections through the lens of education and training

The new BLS education and training categories provide information on the typical path to enter and how to become competent in occupations; they not only are a useful resource for career exploration but also provide insight into the expected demand for workers by education level and other types of career preparation

Dixie Sommers
and
Teresa L. Morisi

Students and career changers want to know what preparation is needed for entry into various careers or, alternatively, what types of career opportunities may be available for a given level of preparation. The counselors, teachers, parents, and others who assist the students also need this information. To better meet this need, the Bureau of Labor Statistics (BLS) has introduced a new set of education and training categories to depict the preparation that individuals need to enter and to become competent in specific occupations.

While these categories were developed specifically for users interested in career exploration and guidance, other data users are interested in this information as well. To help them make decisions on investments and human resource planning, policy makers, businesses, and others want to know what the expected demand may be for workers with various levels of education attainment and other preparation. While not directly depicting demand by education attainment, the BLS education and training categories provide insight into the expected demand.

This article examines the 2010–2020 employment projections through the lens of the new education and training categories. The results indicate, for example, that the fastest projected employment growth, 21.7 percent over the decade, is among occupations with a master's degree as the typical entry-level education needed, while the largest number of projected new jobs, 7.6 million, is among occupations with a

high school or equivalent as the typical entry-level needed.

This article begins by discussing what the new categories are, why BLS changed from the previous categories, and how BLS assigned the new categories. Next, it examines how the assignments are distributed across major occupation groups and across the intersections of the three dimensions of the new system. Then summary results are presented using the 2010–2020 employment projections, as well as wage information from the Occupational Employment Statistics program. In addition, the article discusses the projections for the entry-level education categories, exploring the results by the on-the-job training (OJT) and related work experience dimensions.

In this exercise, BLS presents its approach to a problem that labor market analysts across the globe face. All analysts need a way to generalize and summarize employment trends by education and other preparation—a way that requires developing some construct to represent the complexities of how labor markets intersect with education and other preparation for work. The article concludes with a brief review of how other analysts, including those in Canada and Europe, are addressing this problem.

What the new categories are

The path for entry and competency. Some occupations have several paths by which a prospective worker can enter, while others have a single

distinct path. An important part of the path is the education that one needs to enter the occupation. For some occupations, a certain level of education is universally required, while for others, it is not as clear-cut. Consider two legal occupations: lawyers and paralegals. Prospective lawyers need to graduate from law school after completing a bachelor's degree. Paralegals, however, can enter the occupation with one of three formal education levels—a postsecondary nondegree award, an associate's degree, or a bachelor's degree.

Another part of the path is whether prior work experience is needed for entry. Such work experience is related to the current occupation a worker is entering, rather than general work experience through which the individual may develop more general skills or work habits. Many of the occupations with a work experience requirement are first-line supervisors or managers who need to have experience in the field that they are supervising or managing. Entrants to some nonmanagerial occupations may also need related work experience.

For some occupations, education can be substituted for work experience and vice versa. An example is the occupation chefs and head cooks. A prospective chef or head cook could enter the occupation with a degree from a culinary school and no prior work experience, or in lieu of formal education, he or she could enter with years of work experience as a lower-level cook.

OJT is also an important part of the path. Such training is needed in many occupations for a person to become competent at performing the occupation. To be “competent” means that someone is qualified to perform the occupation independently. OJT is normally attained after one is employed in an occupation. It can be an apprenticeship, which is a formal relationship between a worker and a sponsor. Apprenticeships are most common in construction occupations, such as electricians, stonemasons, or carpenters. In other occupations, entrants need to complete an internship or residency. Each is found mainly in teaching and medical occupations and may be required for state licensure or certification. In addition, in some occupations, workers need less formal types of OJT to become competent.

BLS sought the best way to depict these requirements and devised the new education and training categories that are being used for the first time with the projections of employment from 2010 to 2020. The new categories include assignments in three different dimensions that make up a path: (1) typical education needed for entry, (2) work experience in a related occupation, and (3) typical OJT needed to attain competency.¹ The BLS data show the

projected demand for occupations, and the categories indicate the education and training characteristics for occupations in the base year of 2010. The data presented in this article summarize the projected employment trends from the 2010–2020 National Employment Matrix by category and by path. Thus, the data represent the trend for occupations assigned to each category or path. The data do not specifically indicate the demand for workers by education attainment, such as demand for college graduates, nor do they indicate or project the educational attainment of the workforce.

The education and training assignments represent a typical path. The assignments in the education and training system are given to each of the 749 detailed occupations for which BLS publishes employment projections. The assignments for entry-level education, work experience in a related occupation, and OJT go together, in that they represent the typical path to enter an occupation and become competent at performing it. BLS analysts decide the “typical path” after reviewing and analyzing various data sources and qualitative information, as described in the section on how the categories were assigned (page 16).

Typical entry-level education and work experience in a related occupation are “preemployment” qualifications, while typical OJT usually occurs after one is employed. Although some occupations may have more than one path for entry, only one path is assigned in the system. The “typical path” holds even for those occupations, such as the chefs and head cooks example mentioned earlier, in which formal education and work experience may be substituted for each other. If an occupation has multiple paths for entry, they are discussed in the narratives in the *Occupational Outlook Handbook*.

Preemployment requirements: education and work experience. The first category in the path is the typical education level needed for one to enter an occupation. The assignments include five postsecondary levels (doctoral or professional degree, master's degree, bachelor's degree, associate's degree, and postsecondary nondegree award). Other assignments are some college, no degree; high school diploma or equivalent; and less than high school.² Note that the education level assigned to an occupation is the typical level most workers need to enter. (BLS economists arrived at the typical level by analyzing data and other research; see the section on page 16 on how the categories were assigned for more information.) In the paralegals example mentioned earlier, several education levels are possible for entry. The education assignment for paralegals is “associ-

ate's degree," because BLS economists determined it to be the typical education needed for entry. Lawyers are assigned "doctoral or professional degree."

The second preemployment category is work experience in a related occupation. This metric captures work experience that employers commonly consider necessary or commonly accept as a substitute for more formal types of training or education. The work experience is occupation specific; that is, it is in a related occupation that provides experience related to the current occupation that a worker is entering and can be transferred to another job in the same occupation. Specific work experience is distinct from general work experience, through which the individual may develop more general skills or work habits. The assignments are a measure of time (more than 5 years, 1–5 years, less than 1 year, or none). As just noted, many occupations for which work experience in a related occupation is needed are first-line supervisors and managers, who need experience in the occupations they will supervise. For example, architectural and engineering managers typically have more than 5 years work experience in architectural or engineering occupations before becoming managers. Some nonmanagement occupations require work experience in a related occupation; real estate brokers, for example, typically need between 1 and 3 years of work experience as a licensed real estate agent.

Postemployment requirement: on-the-job training. Occupations also receive an assignment that represents the typical OJT needed for a worker to attain competency in the occupation. This training is occupation specific; it is not job specific. Occupation-specific training can be transferred to another job in the same occupation. For example, the training an electrician receives through an apprenticeship can be transferred to another electrician job. Internship-residency is another assignment for this category, although it is not strictly a postemployment requirement but tends to come before one is employed. For example, after completing their doctorate program, podiatrists must complete a residency program that lasts 3 years. In most states, the residency is required before a podiatrist can be licensed to practice.

Other assignments for this category include long-term OJT (more than 1 year), moderate-term OJT (1–12 months), short-term OJT (1 month or less), and none. For example, real estate sales agents typically enter the occupation with a high school diploma and learn their occupation through long-term OJT. Insurance underwriters are assigned "moderate-term OJT" in the system—even though they typically need a bachelor's degree for entry,

they receive OJT as a trainee supervised by a senior underwriter. A fast-food cook is an example of an occupation in which one undergoes short-term OJT.

Why BLS developed the new categories

BLS used an earlier education and training category system from 1995 (with the publication of 1994–2005 projections) through the 2009 publication of the 2008–2018 projections.³ The earlier system assigned 1 of 11 categories to each occupation that represented the "most significant source" of education or training. The 11 categories combined education, work experience, and OJT, and BLS analysts could choose only one category to assign to an occupation. The previous categories included postsecondary education levels ranging from first professional degree to postsecondary vocational award; two categories with work experience—bachelor's or higher degree, plus work experience and work experience in a related occupation; and three OJT categories denoting long-term, moderate-term, and short-term OJT.

The previous system was replaced for a number of reasons. One is that since each occupation received just a single assignment to cover education, work experience, and training, it did not provide enough information on the path that a person typically needs to follow to enter an occupation and become competent at performing it. Except for the "bachelor's or higher degree plus work experience" item, the system did not show whether an occupation needed combinations of education, work experience, and training (for example, postsecondary education and some period of OJT), since only one assignment could be made. Only postsecondary education levels were included; no assignments could be made for the high school level and below. In addition, the former categories could be misinterpreted. For example, some users assumed that all occupations assigned an OJT category were high school or less than high school occupations, although this was not the case. Another drawback of the system was that the term *most significant source* was not defined.

How the new categories were developed

The new education and training system is the result of work by BLS economists, with input from data users. BLS staff reviewed the drawbacks of the prior system and developed ways to better represent the typical path of entry and competency. Two rounds of public comment occurred, in November 2008 and September 2010. The latter round included an experimental dataset of about 100

occupations. The BLS received many helpful comments from the public and considered these when devising the final system.

BLS originally proposed adding a licensing category. However, further testing and refinement of the licensing definition revealed some problems, such as how to capture occupations in which a subset requires licensure either in all states or some states. An additional issue is that states also regulate occupations through less-restrictive forms, known as registration and statutory certification, in which a state grants “title” protection to an individual with a certification. These forms of regulation are sometimes referred to as “licenses.” BLS found this information proved too complex to represent accurately, without extensive additional research.

BLS also studied certification as a possible category to include in the classification system. Certification does not fit into the overall concept of the system, however, which is to provide information on what is needed to enter and to attain competency in an occupation. Certification is normally voluntary and is a recognition that a nongovernmental body provides. It can demonstrate competence in occupation-specific skills, job-specific skills, or advanced practice skills. Therefore, certification is generally obtained for a person to advance within an occupation, either to a higher level or to move to a specialized area. In addition, the term *certification* is often confused with academic certificates received from postsecondary institutions. For these reasons, certification is not included in the education and training classification system. Certification, however, is discussed in the narratives of occupational profiles in the *Occupational Outlook Handbook* if it is important for the occupation.

BLS published the final categories on the BLS website in fall 2011, followed by the occupational assignments in December 2011. The 2010–2020 employment projections released on February 1, 2012, were the first to incorporate the new system.

Users should not compare results from the new education and training categories with the previous system. The major difference is that the concepts are not the same. The previous system assigned a single category that represented the “most significant source” of education or training. The concepts for the new system are more clearly defined. The education assignment represents the typical entry-level education, and the assignment in the current system could be different from what was assigned in the past. In addition, occupations could not receive education assignments below the postsecondary level in the previous system. The 2010–2020 projections also are the first to in-

corporate the 2010 Standard Occupational Classification (SOC) system, and some occupations are new and will not have prior assignments.

How the categories were assigned

BLS economists assigned occupations to categories on the basis of analyses of qualitative and quantitative information. Sources of quantitative data included educational attainment data from the American Community Survey (ACS) and the Occupational Information Network (O*NET).

American Community Survey data. The Census Bureau’s ACS collects data on educational attainment, as well as employment by occupation. The BLS published educational attainment data on its website that are based on the ACS microdata files for 2005 through 2009.⁴ These data show the percent distribution of workers 25 years and older employed in an occupation by their highest level of education attained.⁵ The data are particularly useful in analyzing occupations with multiple entry-level education possibilities.

Like any sample survey, the ACS is a household sample survey and is subject to response and coding error, as well as sampling error. The ACS data therefore must be carefully evaluated. In addition, although the Census Bureau’s occupational classification system also is based on the SOC, it does not provide the same level of detail as the BLS shows in the National Employment Matrix. As a result, some detailed SOC occupations shown in the BLS data have the same educational attainment data because they are combined in the Census Bureau’s occupational classification system.

These data show the highest level of educational attainment of individuals working in the occupation. Thus, the data may show higher or lower educational attainment than the assignment given in the classification system for typical entry education. For example, the ACS data show that a majority of advertising sales agents have a bachelor’s degree, but the education category assignment for the occupation is “high school diploma or equivalent,” because workers typically enter the occupation with the lower level of education. In other cases, the category assignment reflects a higher level of education than the attainment data show. For example, occupational therapists are assigned to the master’s degree category, but more than half have only a bachelor’s degree according to the ACS data. The entry requirements for occupational therapists have changed over time, and current entrants typically need a master’s degree.

In some cases, the ACS data may show workers with educational attainment much higher than is needed for their occupation. In fact, the ACS data show that every occupation has some share of workers with a bachelor's degree. For example, according to the ACS data for 2005 through 2009, among workers 25 years and older, 12.5 percent of waiters and waitresses and 13.0 percent of bank tellers had bachelor's degrees as their highest level of education attainment, although these occupations have education assignments of less than high school and high school diploma in the BLS category system, respectively.⁶ Some of these results may be response or coding error, or college-educated workers may in fact be in every occupation, even those in which most workers have less than a high school diploma. Some workers choose occupations that do not necessarily mesh with their educational attainment. For example, they may have family responsibilities that cause them to choose an occupation for which they are over qualified because it has flexible hours. In addition, college-educated workers may not be able to find a job that uses the education they possess, sometimes referred to as "mal-employment," which can be more likely during recessions.⁷ Even if workers have the right level of degree, they may also experience mismatches between the field of their degree and the fields of degrees required in the jobs available. In other cases, workers simply choose occupations below their education level because they prefer them or they may be working in them while pursuing other options.

When assigning education categories, BLS economists reviewed ACS 2005–2009 educational attainment distributions for occupations by two age breakouts: ages 18 to 29 and 30 and older. For most occupations, the younger age group was considered to better represent the education level needed by workers who are entering the occupation; for occupations requiring a doctoral or professional degree, the older cohort was more appropriate given the time required to attain advanced degrees.

Other resources used to assign categories. BLS economists also analyzed data from the O*NET, a product of the Employment and Training Administration of the U.S. Department of Labor. O*NET's data on education, work experience, and training requirements for occupations come from a survey of workers in the occupation and of occupational experts and analysts. A limitation of the O*NET data was the small sample sizes for some of the occupations surveyed.

Economists at BLS also used qualitative information to assign categories. They interviewed persons who were knowledgeable about education and training requirements

for the occupations. They obtained information from employers, workers in the occupation, training experts, and representatives of professional and trade associations and unions, among others. BLS economists also reviewed information from regulatory authorities (if they existed for an occupation) and actual job postings for the occupations.

A summary look at the assignments

Education categories by major occupation group. How are the education and training categories distributed across major occupation groups? The SOC system groups occupations according to the type of work performed and not according to education or skill level. Thus, finding a range of typical entry-level education categories within any of the 22 SOC major occupation groups is not surprising. These distributions indicate that analysis of occupations by the education categories is best done at the detailed occupation level, rather than at the major group level.

Four major groups had six education categories represented: education, training, and library occupations; health-care practitioners and technical occupations; personal care and service occupations; and transportation and material moving occupations. Two major groups with the least dispersion across education categories had only two categories represented: building and grounds cleaning and maintenance occupations and construction and extraction occupations, in which only the high school diploma and less than high school education categories occurred. (See table 1.)

Conversely, each education category is found across multiple major occupation groups, with the high school diploma or equivalent assignment found in 20 of the 22 major groups (all but computer and mathematical occupations and life, physical, and social science occupations). The bachelor's degree assignment appears in 15 major groups and the associate's degree in 13 major groups. The least dispersion across major groups is for the doctoral or professional degree (5 groups), master's degree (6 groups), and some college, no degree (6 groups). (See table 1.)

Multiple dimensions of occupational preparation. An advantage of the new BLS education and training categories is that it helps data users examine paths to entry and competence, that is, the intersection of education, related work experience, and OJT. Educational attainment is an important preparation for entry into many occupations but often does not tell the whole story. Individuals making career decisions, counselors and others who assist these individuals, and those planning and funding workforce development activities need to understand the training

Table 1. Number of occupations assigned to education categories, by major occupation group

SOC	Major occupation group	Typical education needed for entry									Number of education categories represented
		Total, all occupations	Doctoral or professional degree	Master's degree	Bachelor's degree	Associate's degree	Postsecondary non-degree award	Some college, no degree	High school diploma or equivalent	Less than high school	
00	Total, all occupations	749	25	29	154	47	42	6	350	96	8

and related work experience dimensions in addition to educational attainment. The following discussion examines how detailed occupations are distributed across these multiple dimensions.

While high school completion is the typical entry-level education in 350 occupations, a high school diploma alone is not sufficient. Individuals preparing for these occupations can expect to face additional training requirements, often of significant length. Among the 350 high

school occupations, only 28 do not typically require OJT to attain competency. Of the occupations with an OJT assignment, the largest numbers are in the moderate-term OJT category (159 occupations) and in the short-term OJT category (100 occupations). Another 49 are in the long-term OJT category, and 14 are assigned to the apprenticeship category. Only one high school occupation has no OJT or related work experience required.⁸ (See table 2.)

Concerning work experience in a related occupation,

651 of the 749 occupations typically have no such requirement for entry. Of the 98 occupations with a work experience assignment other than “none,” 58 are manager or supervisor occupations in which experience in the type of work managed or supervised is typically needed for entry or may be substituted for other entry requirements.⁹ The largest numbers of occupations with a related work experience assignment other than “none” have an entry-level education assignment of bachelor’s degree (38 occupations) and high school diploma or equivalent (42 occupations). (See table 2.)

Most occupations with a related work experience assignment do not also have an OJT assignment. Of the 98 occupations with a related work experience assignment other than “none,” only 31 have an OJT assignment other than “none.” (See table 2.) These 31 occupations are a diverse list, representing 12 of the 22 major occupation groups and 5 of the 8 education categories.

Results for the 2010–2020 projections

Summary results. In their analysis of the 2010–2020 occupational projections, Lockard and Wolf presented summary data for each of the three dimensions of education, training, and related work experience.¹⁰ (See table 3.) These data are totals for all occupations assigned to each category. For example, employment in 2010 for the bachelor’s degree education category was 22.2 million and is projected to grow by 16.5 percent to 25.8 million by 2020. These numbers represent the sum of employment in all 154 occupations assigned bachelor’s degree as the typical entry-level education. Note that these data do *not* represent the number of workers with bachelor’s degrees in 2010 or projected to have such degrees in 2020.

The summary information in Lockard and Wolf shows what the BLS projections indicate about the changing demand for entry-level workers with various types of educational preparation. The fastest projected growth is among occupations with master’s degree and doctoral or professional degree as the typically entry-level education needed, while the slowest growth is among occupations with high school diploma or equivalent. These data are useful because demand for workers with particular levels of education attainment is largely driven by growth or decline in employment in the occupations in which such attainment is typically required for entry. The BLS projections depict the demand by occupation. Actual labor market activity may be somewhat different. Given the complexity of entry paths in certain occupations, some employers may require or prefer different education entry levels

than the “typical” levels identified by BLS, and employers may adjust entry requirements in times of high or low unemployment. Also, within an education attainment level, demand may vary by the field of study related to the occupation. Indeed, the BLS projections indicate, for example, that bachelor’s degree occupations in the computer and mathematical occupations group are projected to grow by 22.9 percent between 2010 and 2020, much faster than the 13.7 percent growth projected for bachelor’s degree occupations in the education, training, and library group.

For the OJT dimension, Lockard and Wolf show that the fastest growth is projected for occupations assigned to the apprenticeship category, at 22.5 percent compared with 14.3 percent for all occupations. This category includes mainly construction occupations, which are projected to grow at above average rates but are not expected to regain all the jobs lost during the 2007–2009 recession. For the work experience in a related-occupation dimension, the fastest projected growth is among occupations in which no such experience is typically required. Among occupations with a work experience assignment other than “none,” the most rapid projected growth is a below-average 13.0 percent change over the decade for the less than 1-year group. (See table 3.)

Education and training requirements and wages. How do wages vary across the education and training categories? Table 3 and chart 1 show the May 2010 median annual wages for the occupations assigned to the various education, work experience, and OJT categories. These summary-level data from the BLS Occupational Employment Statistics program indicate the wage variation. The OES data are medians for all workers, including both entry-level and experienced workers, while the education and training assignments are for entry-level preparation. How wages vary when education, work experience, and OJT are combined to show paths of entry and preparation is discussed in the following paragraphs.

Across the education categories, the wage patterns approximate what would be expected from other information: wages are generally higher as the typical entry-level education rises.¹¹ The results differ somewhat from this expectation, however, because other characteristics affect wages, including related work experience, OJT, and the field of study related to the occupation.

The highest median annual wages, at \$87,500, are for occupations in the doctoral or professional degree category—more than twice the \$33,840 median for all occupations. Median annual wages are similar for the three next-highest education categories: master’s degree at \$60,240,

bachelor's degree at \$63,430, and associate's degree at \$61,590. (See table 3 and chart 1.)

The somewhat lower median wage for master's degree occupations compared with bachelor's and associate's degree occupations conflicts with the expectation that investment in additional education generally results in a return of higher wages. Wages are affected by factors besides the level of

degree, however, including the field of study relevant to the occupation. Returns are generally higher in some types of occupations—notably those in management and in technical fields—than others with the same or higher education requirements, such as counseling or social work.

Chart 2 shows the distribution of employment by ranges of median wages for the master's, bachelor's, and associ-

ate's degree occupations. The occupations in these three education categories have about the same shares of employment in the median wage ranges more than \$75,000 to \$100,000, more than \$50,000 to \$75,000, and less than median for all occupations (\$33,840). In the highest-paying median wage range (more than \$100,000), however, only one master's degree occupation appears—political scientists, at \$107,420—and one associate's degree occupation—air traffic controllers, at \$108,040. Each of these occupations accounts for 0.3 percent of employment among all occupations in its education category. Eight bachelor's degree occupations have median wages above \$100,000, however, and they account for 7.7 percent of the jobs in bachelor's degree occupations: chief executives; architectural and engineering managers; natural sciences managers; computer and information systems manag-

ers; petroleum engineers; marketing managers; financial managers; and airline pilots, copilots, and flight engineers. All the bachelor's degree occupations in the highest wage range require education in business, science or engineering, or another technical field, and all but petroleum engineers require related work experience or, in the case of airline pilots, copilots, and flight engineers, moderate-term OJT.

In wage range from \$33,840, the median wage for all occupations, to \$50,000, the master's degree occupations have nearly twice the share of employment (20.1 percent) than do bachelor's degree occupations (11.4 percent), and associate's degree occupations fall in between (16.5 percent). (See chart 2.) The seven master's degree occupations in this wage range include four community and social service occupations (marriage and family therapists, mental health

Chart 1. Median annual wages for occupations by education and training category, May 2010

SOURCE: U.S. Bureau of Labor Statistics, Occupational Employment Statistics.

counselors, all other counselors, and healthcare social workers); two education, training, and library occupations (curators and farm and home management advisors); and one healthcare technical occupation (all other therapists). The mental health counselors occupation pulls the overall wage for this group down, because it is a relatively large occupation, with low median wages of \$38,150.

In chart 1, for the two categories between high school diploma and associate's degree, the wages differ substantially, with \$34,220 for occupations in the postsecondary nondegree award category and \$44,350 for those in the some college, no degree, category. The latter category contains only six occupations, all of which require either related work experience or OJT, or both. For the high school diploma category, median annual wages of \$34,180 are similar to the postsecondary nondegree award category, perhaps reflecting the fact that nearly all occupations in the high school category also require related work experience or OJT, or both. As expected, wages for occupations in the high school category are much higher than the \$20,070 for occupations

in the less than high school category.

When wages are considered by the related work experience categories, occupations typically requiring more than 5 years of related work experience have much higher wages, at \$87,410, than for any other work experience category. Most of these occupations are managers or supervisors. Occupations in the 1 to 5 years of related work experience category had median wages of \$52,000, much more than the median for all occupations. Wages differed little between the less than 1 year and no work experience categories, at \$32,320 and \$31,260, respectively. (See chart 1.)

For the OJT categories shown in chart 1, occupations with an OJT assignment of "none" had the highest median wage, at \$56,680. The 241 occupations in this group ranged widely across all the education categories, as seen in table 2. Among occupations with OJT assignments other than "none," wages were generally higher with more training. Median wages were similar between the apprenticeship occupations (\$44,550) and long-term OJT occupations (\$45,370). Wages for these two groups were significantly

Chart 2. Percent of employment by range of May 2010 median wages, master's, bachelor's, and associate's degree occupations

SOURCE: U.S. Bureau of Labor Statistics.

below the \$55,580 for the internship-residency group. The internship-residency group includes a mix of highly paid medical practitioners as well as teaching and counseling occupations that pay above average but much less than the medical practitioners. Occupations with moderate-term OJT are typically paid much more (\$35,650) than those with short-term OJT (\$22,810). (See chart 1.)

Value of work experience and training. Work experience and OJT can be important parts of the path for entry and competency in an occupation. Looking across the three dimensions of the system—the path—provides additional insight into the value of work experience and OJT regarding pay and job opportunities. Out of the 192 possible combinations of education, work experience, and OJT, 59 paths include one or more occupations. Some of the paths, with one occupation, have very large employment. For this analysis, the 59 paths were further narrowed to the 22 that had 10 or more occupations and/or 2010 employment of 1 million or greater. These paths are shown in table 4, which displays the paths sorted by education assignment and then by work experience and OJT. All typical entry-level education categories are represented, except for some college, no degree. Two of the paths each have one large occupation with employment of greater than 1 million.

An analysis of these paths reveals the following three observations. First, for occupations assigned the same

entry-level education, those that require work experience generally pay more than those without it. Second, the fastest growing paths include many healthcare occupations. Last, most job openings (new jobs and replacement positions) are projected in paths with lower pay, little formal education, no work experience, and little or no OJT.

The 2010 median annual wages for the 22 selected paths are shown in table 4. Of these paths, five are bachelor's degree paths. The two bachelor's degree paths with work experience (Bachelor's/More than 5 years/None and Bachelor's/1 to 5 years/None)¹² have higher median wages than the three bachelor's degree paths that do not need work experience. Occupations that typically need a bachelor's degree and work experience are, for the most part, managers, directors, administrators, and others with managerial-type responsibilities. The median wage, \$116,290, for the Bachelor's/More than 5 years/None path is the highest for the bachelor's degree groups shown. This group consists entirely of management occupations.

For the three associate's degree paths shown, the path with work experience also pays more than those without. The occupation in the Associate's/1 to 5 years/None path is general and operations managers, a large occupation that had employment of 1.8 million in 2010 and a median wage of \$94,400. The two associate's degree paths with no work experience paid much less. Associate's/None/Moderate-term OJT had a median wage of \$41,470 and

Employment Projections

¹ The paths do not add up to the total. SOURCE: U.S. Bureau of Labor Statistics.

Associate's/None/None occupations paid \$57,180.

For high school occupations, four paths with work experience are shown in table 4. Two of these work experience paths are paid much more than any of the other high school paths. High school/More than 5 years/None had a median wage of \$63,730 in 2010. This path includes managerial and first-line supervisor occupations. High school/Less than 1 year/Long-term OJT has one large occupation (business operations specialists, all other) that paid a median wage of \$62,450 in 2010.

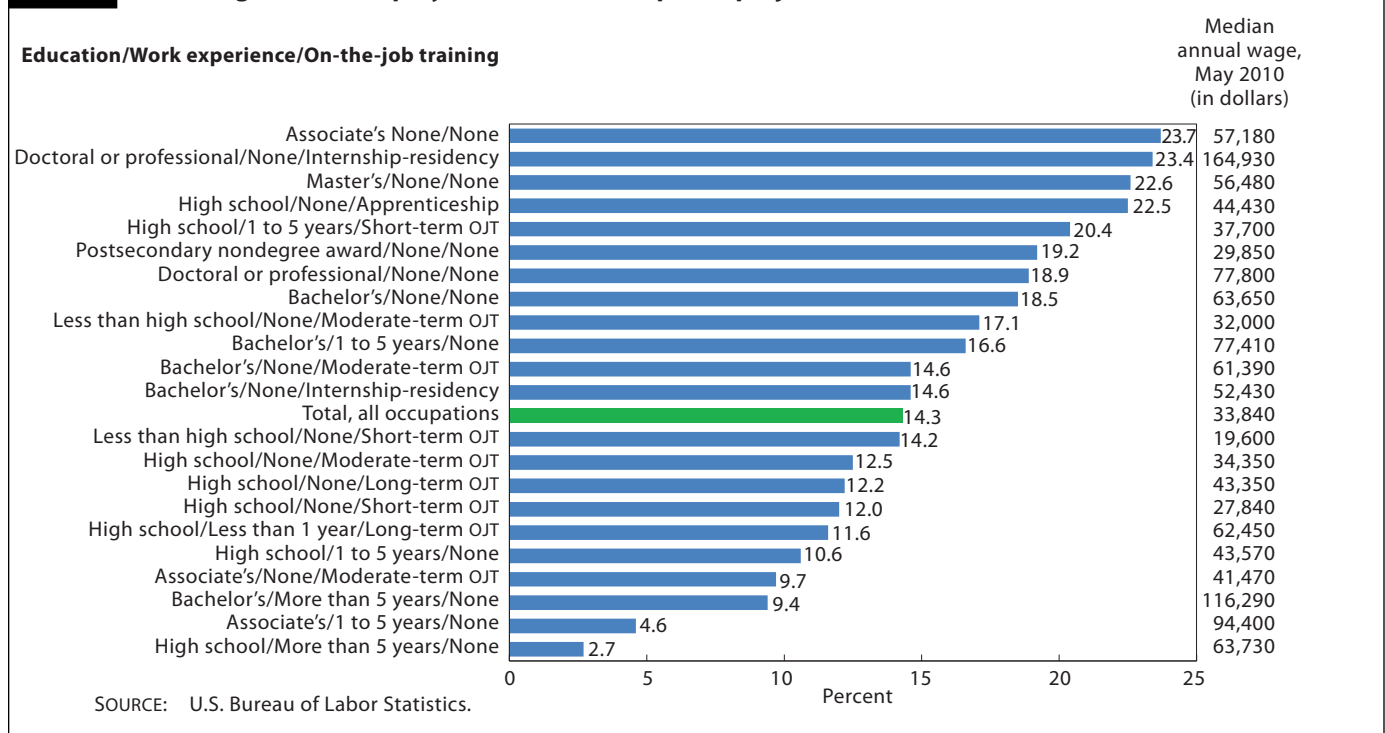

The High school/None/Apprenticeship path, which mainly includes construction occupations, had a median wage of \$44,430 in 2010. This group paid somewhat more than two paths with work experience: High school/1 to 5 years/Short-term OJT, at \$37,700, and High school/1 to 5 years/None, at \$43,570. Close to the apprenticeship path in terms of pay was High school/None/Long-term OJT, at \$43,350. Most occupations in this path are in production; installation, maintenance, and repair; and arts, design, entertainment, sports, and media.

Comparing the median wage for all paths shown in the table 4, one will find that four paths pay less than the total median wage of \$33,840—both Less than high school paths and the High school/None/Short-term OJT and Postsecondary nondegree award/None/None paths. This postsecondary nondegree award path includes some low-

er-level healthcare occupations, such as nursing aides and orderlies; a few service occupations, such as hairstylists; and some technician and repairer occupations. The three highest-paid paths shown are Doctoral or professional/None/Internship-residency, at \$164,930; Bachelor's/More than 5 years/None, at \$116,290; and Associate's/1 to 5 years/None, at \$94,400. The Master's/None/None path paid less, at \$56,480, than several occupational paths with less education. The Master's/None/None path contains some lower-paying social work occupations, including rehabilitation counselors; education, guidance, school, and vocational counselors; and healthcare social workers.

The projected percent growth in employment for the selected paths is shown in chart 3. The fastest growing paths are heavily represented by healthcare-related occupations. Other occupations represented in the fastest growing paths are in science and engineering, social sciences, and construction. The Associate's/None/None path has the fastest projected growth, 23.7 percent, and includes rapidly growing occupations in healthcare, such as physical therapy and occupational therapy assistants, diagnostic medical sonographers, dental hygienists, respiratory therapists, registered nurses, and several technologists and technicians. The Associate's/None/None path also includes occupations that are various types of science technicians, engineering technicians, and drafters. The

Chart 3. Percent growth in employment for selected paths, projected 2010–2020

Doctoral or professional/None/Internship-residency path is projected to grow by 23.4 percent and largely consists of physicians and surgeons and various dentist occupations. The Master's/None/None path is projected to grow by 22.6 percent. This path mainly includes healthcare occupations, such as occupational therapists and physician assistants; counseling and social work occupations, including rehabilitation counselors and healthcare social workers; and social science occupations, such as historians and sociologists. The construction occupations make up all but one of the occupations assigned to the High school/None/Apprenticeship path, which is projected to grow by 22.5 percent. Rapid growth is projected for many construction occupations as the construction industry recovers from the 2007–2009 recession; however, this growth represents only a partial recovery of jobs lost.¹³ Of the 12 paths that are projected to grow faster than the overall average of 14.3 percent, 9 typically need some level of postsecondary education.

The paths projected to grow the slowest are High school/More than 5 years/None; Associate's/1 to 5 years/None; and Bachelor's/More than 5 years/None. The High school/More than 5 years/None path contains an occupation projected to decline: farmers, ranchers, and other agricultural managers. The lone occupation in Associate's/1 to 5 years/None is the large and well-paying general and operations managers, which is projected to grow by 4.6 percent. The Bachelor's/More than 5 years/None path contains six management occupations.

For the most part, occupations in paths projected to have the most job openings from 2010 to 2020 are those with large employment numbers in 2010 and that require little formal education, no work experience, little or no OJT, and have low pay. (See chart 4.) Job openings come from both economic growth (new jobs) and the need to replace workers who permanently leave occupations, and the number of openings due to replacing workers is generally larger than the number of new jobs. The path projected to have the most job openings is also the lowest-paid path on the chart: Less than high school/None/Short-term OJT, with 14.6 million job openings and 4.8 million of those being new jobs. Next are two high school occupations: High school/None/Short-term OJT, with 8.0 million job openings (2.6 million from growth), and High school/None/Moderate-term OJT, with 6.1 million job openings (2.3 million from growth).

Although the top three paths with the largest number of job openings do not need postsecondary education, the path with the fourth largest number of job openings does. The Bachelor's/None/None path is projected to have 4.3

million job openings from 2010 to 2020, and 2.0 million of those are to be new jobs due to growth. This path is the fourth largest in occupational employment in 2010, at 10.8 million, and has an assortment of occupational groups.

Labor market analysis and required education

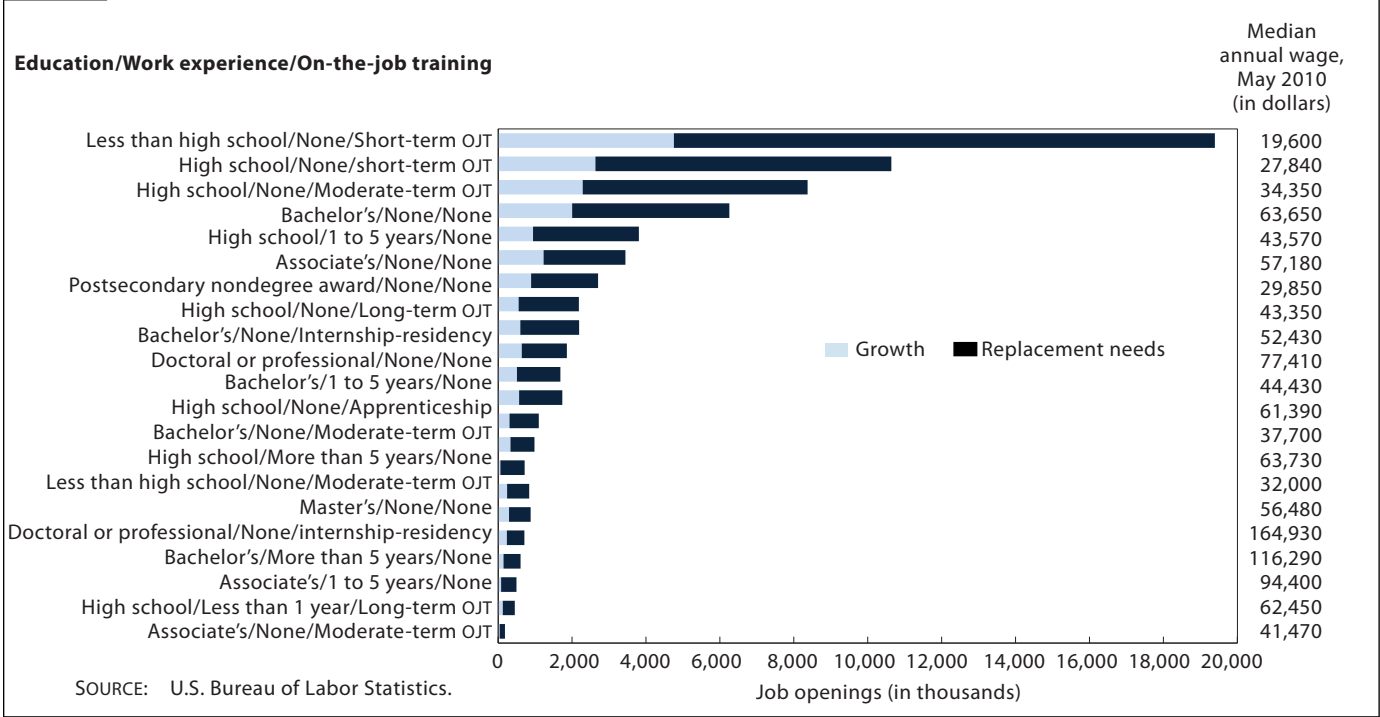

As noted at the beginning, BLS is presenting its approach to a problem that labor market analysts face across the globe. These analysts need a way to generalize and summarize employment trends by education and other preparation, which requires developing some construct to represent the complexities of how labor markets intersect with education and other preparation for work.

A review of several other studies finds two approaches to generalizing and summarizing employment trends. The first is a classification approach in which occupations are categorized according to education and training. A second approach is computational, in which the base year and projected employment are distributed by educational attainment and then employment is reaggregated by the educational attainment categories, resulting in projected labor demand by education level. In both approaches, some analysts (but not BLS) also develop projections of the labor force by education or skill level and compare these projections to the labor demand by education level to depict projected supply-demand conditions by education level.

The BLS approach is an example of the first approach, since each SOC occupation for which projections are produced receives the education and training assignments. The SOC itself does not consider education or training level in the design of the classification. Other occupational classification systems, however, build education level into the occupational classification itself using a skills hierarchy. The International Standard Classification of Occupations (ISCO)¹⁴ and Canada's National Occupational Classification (NOC)¹⁵ are examples of such classifications.

The Canadian Occupational Projections System produces demand projections by broad skill level, using the NOC's hierarchy of education level or training usually required for a person to work in a given occupation. This process is straightforward. The projections for individual occupations are summed according to the NOC hierarchy, resulting in employment by five skill levels: management occupations and occupations usually requiring university education, college education or apprenticeship training, high school diploma, and only OJT.¹⁶ The Canadian analysts also produce labor force projections by level of education attainment and then convert these labor force projections to broad skill level using the distributions of the

Chart 4. Job openings due to growth and replacement needs for selected paths, projected 2010–2020

nonstudent labor force by education and skill level. They also discuss in detail the reasons why a worker's education and the requirements of his or her eventual occupation may be quite different, noting that, for example, in occupations typically requiring only OJT, about 30 percent of the workers have a postsecondary education.¹⁷ This finding is similar to the comparison of the BLS education categories and the ACS educational attainment data noted earlier.

A broadly applied example of the second approach is found in Europe. The European Center for the Development of Vocational Training, referred to by its French acronym CEDEFOP (Centre Européen pour le Développement de la Formation Professionnelle), has produced analyses of skills supply and demand in Europe. The models used include production of demand by occupation and translation of this information into demand by qualification. Qualifications are broadly defined based on education attainment as three groups: high, medium, and low. Employment demand projections are translated to qualifications based on continuation of past patterns of employment by broad qualification level within both occupations and industries.¹⁸ As in Canada, the CEDEFOP model also includes components for projecting the labor force by education attainment and for allocating the labor force to occupations, assuming historical patterns of unemployment by qualification categories will continue.

The CEDEFOP authors note that “there is no simple one-

to-one relationship between occupation and qualification”¹⁹ but explore how these are changing over time. Like the Canadian analysis, CEDEFOP examines the nature of the differences between the characterization of occupational requirements and the actual distribution of workers in occupations by their level of education attainment, identifying a variety of types of mismatches.²⁰

In the United States, an example of the second approach, but also including the first approach, is found in a recent working paper by Neumark, Johnson, and Mejia.²¹ The study examines the question of whether the pending retirement of the baby boom generation will result in a skills gap in the U.S. labor market. The authors use the previous 11 BLS education and training categories to depict demand by education attainment, encountering the weaknesses of these categories described earlier. The authors also project education requirements by assuming a steady rate of growth between 2008 and 2018 in the education distributions within occupations.

Also in the United States, a Georgetown University report depicts the projected education requirements of jobs by occupation using the distribution of 2008 employment by occupation and education attainment and projecting the change in this distribution to 2018.²² The Georgetown authors assume that “the present distribution of education among the employed prime-age population is the best single indicator of present demand for education.”²³

These studies, in the United States and elsewhere, demonstrate the complexity of relating education to employment requirements. All rely on employment demand by occupation as the source of demand for workers with various educational qualifications. The studies differ in their consideration of the nature of mismatches between the education that workers have and the education and training that occupations require. The new BLS education and training categories and the 2010–2020 employment projections provide a new data set for future research on this important topic.

IN SUM, the new BLS education and training categories provide information on the typical path that one needs to enter an occupation and to become competent at perform-

ing it. They provide useful information not only for career seekers and persons who advise them but also for policy makers, businesses, and others with interest in education and training needs. When the categories are applied to the 2010–2020 employment projections, they show that faster growth is projected in occupations in which postsecondary education is typically needed for entry, and in terms of OJT, the fastest growth is projected in occupations that typically require an apprenticeship. The system also allows analysis across its three dimensions, and the three dimensions make up a “typical” path. The fastest growing paths from 2010 to 2020 are heavily represented by healthcare occupations. Individuals in occupations with the same entry-level education requirement and who need work experience earn more than those who do not need work experience. □

NOTES

¹ The education and training assignments for all occupations in the 2010 National Employment Matrix are shown in Employment Projections Table 1.12, http://www.bls.gov/emp/ep_table_112.htm.

² Definitions for the individual categories and assignments are presented at http://www.bls.gov/emp/ep_definitions_edtrain.pdf.

³ The prior system was introduced in *Employment Outlook: 1994–2005. Job Quality and Other Aspects of Projected Job Growth*. Chapter III. The Educational Requirements of Jobs. BLS Bulletin 2742, December 1995. It was further described in “A New Way to Classify Occupations by Education and Training,” *Occupational Outlook Quarterly* (Winter 1995–1996).

⁴ These data are available in Employment Projections Table 1.11 at http://www.bls.gov/emp/ep_table_111.htm.

⁵ BLS produces employment projections for 749 occupations; these occupations match the structure that the Occupational Employment Statistics (OES) program used to publish 2010 data. OES occupations are classified on the basis of the Standard Occupational Classification (SOC) system. However, OES data do not exactly match the updates made to the SOC in 2010. OES is transitioning to the 2010 SOC, but the change will not be fully implemented until the 2012 reference year.

Impact of commodity price movements on CPI inflation

An analysis of price movements of four commodities—crops, animal slaughter and processing, dairy, and oil and gas—reveals that only oil and gas prices had a considerable impact on CPI inflation; thus, even large increases in the prices of the first three of these commodities do not necessarily contribute substantially to inflation

Richa Ajmera,
Nancy Kook,
and
Jeff Crilley

A worldwide surge in commodity prices that began in late 2006 and ended in mid-2008 generated interest in studying the effects of commodity price movements on consumer prices. During this period, prices for commodity crops nearly doubled while prices for oil and natural gas more than doubled. In a recent article, Bart Hobijn of the Federal Reserve Bank explored the relationship between commodity price changes (for crops, oil, and natural gas) and changes in inflation as measured by the Bureau of Economic Analysis (BEA).¹ Hobijn analyzed BEA's Personal Consumption Expenditures (PCE) Price Indexes from June 2006 through June 2008, to determine the extent to which commodity price swings affected the price of final consumer goods. Hobijn found that the commodity price increases translated into larger price increases in the United States only for those goods most closely related to the commodities in question. The contribution of the price surges to overall inflation was less pronounced.

Building upon Hobijn's work, this article explores the effects of price changes in four commodity groups (crops, animal slaughter and processing, dairy, and oil and natural gas) on the Bureau of Labor

Statistics (BLS, the Bureau) Consumer Price Index (CPI) for various final goods, and on overall CPI consumer inflation, from 2003 through 2008. Although the increases in crop and oil prices, and in natural gas prices, during the years 2006 through 2008 were relatively high, the prices of these commodities exhibited noticeable highs and extreme volatility several years prior to Hobijn's analysis. Numerous factors drove commodity price volatility during this earlier period, the most important of which were fundamental changes to supply and demand, speculative market trading, exchange rate fluctuations, and political conflicts in key producing regions of the globe.

The analysis presented here produces findings similar to Hobijn's. In general, despite large runups in commodity prices, the effects on overall rates of CPI inflation were relatively modest, although certain CPI categories were heavily influenced by the price movements of the commodities examined. In the shorter periods with particularly dramatic price movements, the results were similar: the impact on overall inflation was still relatively modest, whereas the impact of commodity prices was more pronounced on those CPI indexes which were closely related to the commodities. However, unlike Hobijn's piece, this article finds that oil and gas commodity price movements

Richa Ajmera and Nancy Kook are economists in the Office of Prices and Living Conditions, Bureau of Labor Statistics; Jeff Crilley is an industry economist with the U.S. Commodity Futures Trading Commission. Email: ajmera.richa@bls.gov, kook.nancy@bls.gov, or jcrilley@cftc.gov

had an appreciable impact on overall CPI inflation, as well as on the lower level indexes, both in the longer term and in specific years.

The article is divided into three main sections. The first section outlines the methodology employed to conduct the analysis, describes the modified Leontief model used to calculate the importance of different commodities for the production of final goods, and discusses both the underlying assumptions of the study and some of its inherent limitations. The second section delineates the components of the four commodity aggregates used in the analysis. The last section examines the major price movements of each commodity aggregate and their impact on several measures of CPI inflation.

Methodology

The analysis that follows examines input–output data in combination with commodity price index data to estimate price transmission from commodity prices to various consumer price indexes. Input–output data are used to compute the input shares of commodities for different consumer goods. Input shares indicate the percentage of value of a final good, or a set of final goods, that can be attributed to a specific input commodity or to a set of input commodities. For this study, the input shares of crops, animal slaughter and processing, dairy, and oil and gas are calculated for a number of CPI categories and then used to examine how commodity price changes would affect the prices of consumer goods if the entire commodity price change were passed forward to the consumer good.

To calculate input shares, a Leontief model is utilized. The model is based on the premise that an economy consists of interdependent industries. In order to produce output, these industries consume products produced by other industries, and possibly themselves, as inputs to production. The model shows that total demand for a product i is the sum of all intermediate demand (from other industries) and final demand (personal consumption, investment, government spending, and net exports) for the product. The Leontief model presented here excludes investment, government spending, and net exports, to focus on final demand for consumers. Total demand for product i can be expressed mathematically as

$$r_i = a_{i1}r_1 + a_{i2}r_2 + \dots + a_{ij}r_j + \dots + a_{in}r_n + b_i, \\ \text{for } i = 1, 2, \dots, j, \dots, n,$$

where r_i is the total demand for product i , a_{ij} is a technical coefficient expressing the value of i necessary to produce a dollar's worth of product j , b_i is final demand for product i , and n is the total number of industries.

To provide a context for this equation, consider the example of a country with only three industries, one producing commodity i (electricity), another producing commodity j (utility natural gas), and the third producing commodity k (coal). Electricity is consumed both for final demand (as personal consumption) and as intermediate demand in the production of natural gas and coal. Total demand for electricity can then be written as

$$r_e = a_{e,ung}r_{ung} + a_{e,c}r_c + b_e,$$

where $a_{e,ung}$ is a coefficient expressing the value of electricity necessary to produce a dollar's worth of utility natural gas, r_{ung} is total demand for utility natural gas, $a_{e,c}$ is a coefficient expressing the value of electricity necessary to produce a dollar's worth of coal, r_c is total demand for coal, and b_e is final demand for electricity. To complete the model, similar equations could be written to describe total demand for coal and utility natural gas. The complete Leontief model can then be used to determine the share of each commodity input to one another.

In this study, the values for r , a , and b are derived from BEA input–output tables and from input–output tables compiled by former BLS analyst Carl Chentrens.² (For a complete and more technical discussion of the methodology, see Appendix A.) The input shares are then used to examine the impact of changes in commodity prices on the CPI. The effect of commodity price movements is calculated by multiplying the input shares of a given commodity by the change in the producer price index for that commodity.

This method of calculating the contribution of commodity price changes to the CPI assumes that such changes are immediately and fully passed through to the consumer. Previous studies have shown, however, that that is not necessarily the case:³ for some commodities, it can take up to a year for the increases to pass through to consumers. This concern is somewhat mitigated by the fact that average producer prices and consumer prices are compared from one year to the next, as opposed to point-to-point price change comparisons. The former method better captures price levels over the entire year and is less influenced by sharp, short-lived movements. Nonetheless, the assumption of immediate and full passage through to the consumer is one limitation of the study. Also, the input–output tables indicate the composition of final goods in terms of PCE categories. Therefore, in order to examine the CPI categories of interest (such as food and beverages, fuels and utilities, and motor fuel), PCE categories

were mapped to the appropriate CPI categories. The PCE-to-CPI mappings were based on a 2007 jointly published BEA–BLS paper.⁴

Components of commodity aggregates

In examining the effects of price changes for crops, animal slaughter processing, dairy, and oil and gas on the CPI, input shares are calculated with the use of BEA input–output data and price changes of the commodities are measured with producer price indexes (PPIs). Unfortunately, in most cases, currently published PPIs do not correspond exactly to input–output table categories, so aggregate PPIs are created to match commodities in the input–output tables. To achieve this result, standard PPI aggregation methodologies were used to combine detailed PPIs into higher level categories. Exhibit 1 shows the PPIs that were aggregated together to match the BEA input–output codes.

Commodity price movements and the CPI

This section discusses the major factors influencing producer prices for certain commodity aggregates over the period from 2003 through 2008, as well as notable effects of price transmission from each of the four commodity aggregates on consumer prices. Effects from all four commodity aggregates were analyzed for the aforesaid period, as well as for a specific subperiod during which price movements seemed particularly interesting. As mentioned earlier, the focus is on average yearly prices instead

of point-to-point price changes, in order to limit the effects of short-term price spikes.

Crops. As seen in chart 1, from December of 2001 through the end of 2008 the crops PPI (obtained by aggregating current PPIs for fruits and melons; fresh/dry vegetables and nuts; raw cotton; and hay, hayseeds, and oilseeds) was moderately stable in its movement, although volatility increased from June 2006 through December 2008. Historically, crop production has been influenced by a variety of factors, including climate conditions, fluctuations in demand, the distribution of plantings among a variety of crops with different yields, food safety issues, and fertilizer prices. The considerable increase in the crops price measure observed in the 2006-to-mid-2008 timeframe was associated with surging oil prices and U.S. government incentives to increase plantings of corn and soybeans for the production of ethanol.⁵

In recent years, a strong expansion of government-based initiatives promoting ethanol production, such as the Renewable Fuel Standard provision in the 2005 U.S. Energy Policy Act, has affected virtually every aspect of the grains and oilseeds industries.⁶ Ethanol production increased from 3 billion gallons in 2003 to more than 6 billion gallons in 2007.⁷ The Energy Independence and Security Act of 2007,⁸ with its goal of producing 15 billion gallons of cornstarch-based ethanol by 2022, triggered more crop shifts to corn and soybean, in turn lowering supplies of other grains and oilseeds.

During the period from 2006 to mid-2008, climate conditions also were a key factor in the increase in crop prices. World wheat prices were driven upward in 2007 as drought conditions in the United States lowered domestic output. In addition, global wheat supplies were limited by drought in Australia, another major wheat exporter. In early 2008, soybean prices increased substantially because of a shortened soybean season, excessive rainfall and flooding, and reduced yields.⁹

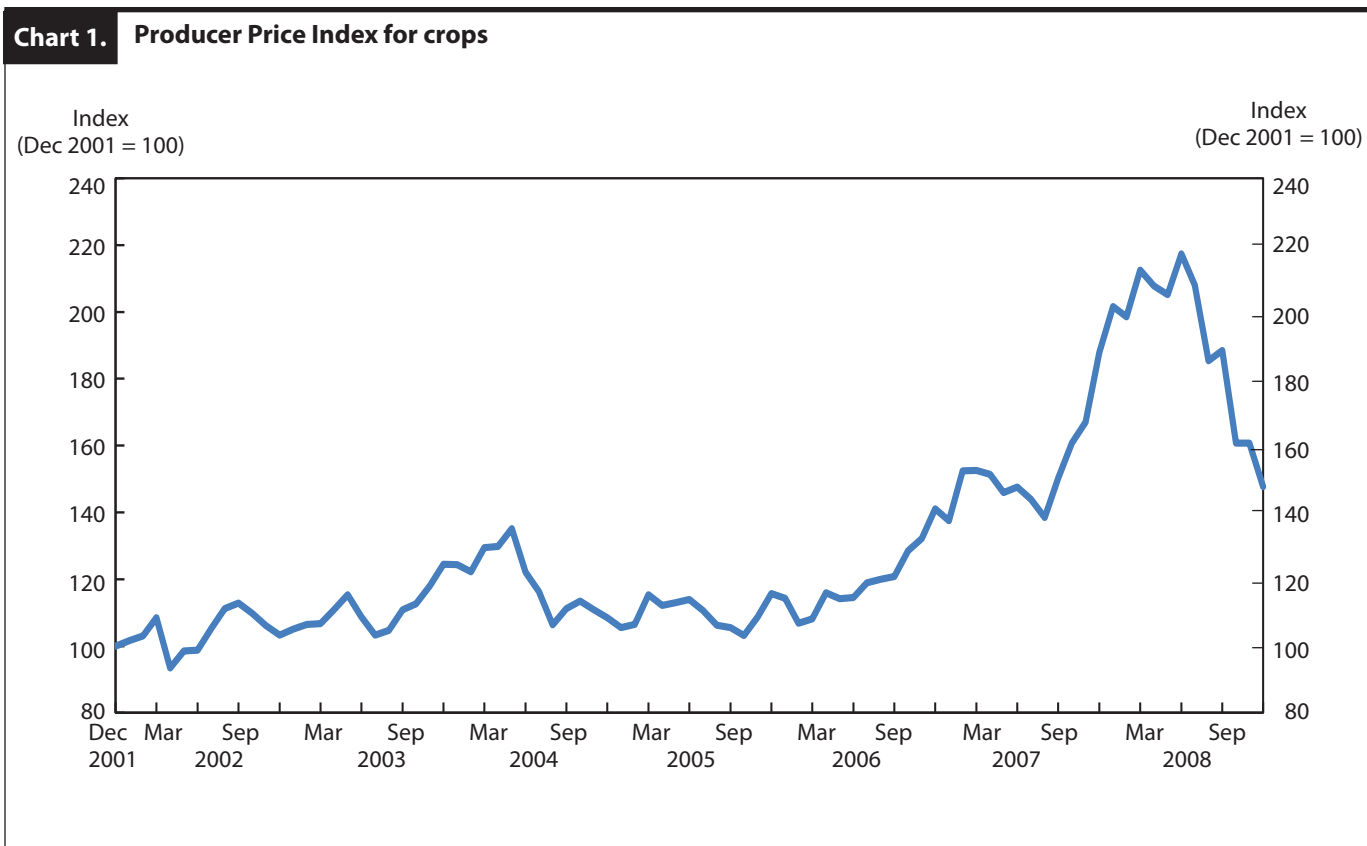

The market volatility stemming from higher ethanol demand and from weather factors appeared to spur increased levels of speculation in food commodity markets.¹⁰ Speculation initially pushed prices higher, but when oil prices tumbled in mid-2008 because of a weakening economy and declines in demand, prices for other commodities (including crops) fell similarly.

In analyzing the effect of commodity price movements on CPI inflation, several different measures were examined. The first column of table 1 shows, for 2007–2008 and 2003–2008, the percentage of the total value of the goods and services covered by each index that can be traced back to

Exhibit 1. Components of commodity aggregates

Input–output commodities	Commodity (C) and industry (I) data ¹
Crops	(C) Fruits and melons, fresh/dry vegetables and nuts (011) (C) Grains (012) (C) Raw cotton (0151) (C) Hay, hayseeds, and oilseeds (018)
Animal slaughter and processing	(C) Meats (0221) (C) Processed poultry (0222)
Dairy	(I) Dairy product manufacturing (3115)
Oil and gas	(C) Natural gas (0531) (C) Crude petroleum (domestic production) (056) (C) Liquefied petroleum gas (0532)

¹ Commodity is PPI commodity; industry is NAICS industry.

crops. The second column indicates the movement of each CPI over the specified periods and was taken directly from CPI tables produced by the Bureau. The third column shows what the movement for the different CPIs would have been had crop prices remained constant. Values in this column were obtained by multiplying the input share of crops by the change in crop producer prices (which represents the contribution of crop price movements to inflation) and then subtracting the result from the corresponding number in the same row in the second column. The numbers are obtained under the assumption that all else remains unchanged. The last column indicates the percentage-point contribution of crop price increases to CPI inflation. Values in this column were calculated by taking the difference of the corresponding values in the same row in the second and third columns and then dividing by the corresponding values in the same row in the second column.¹¹ (A detailed analysis for each year is available from the authors.)

Although crop prices exhibited major movements in recent years, their impact on consumer prices was limited (as can be seen in table 1): even though crop prices increased by 83.18 percent (a 10.62-percent annual compounded rate of change) from 2003 to 2008, the change in the CPI

for all items was less than 20 percent over the same time-frame. Under the methodology and assumptions of this article, had crop prices remained constant and were all else held equal, the all-items CPI movement would have increased at a slightly lower rate of 18.94 percent. Rising crop prices therefore accounted for less than 4 percent of the increase in the all-items CPI from 2003 to 2008. The reason the impact of crop prices on the all-items CPI was minimal was that the input share of crops averaged just 1.05 percent. In the subperiod from 2007 to 2008, the impact was stronger because the crop price changes were greater (59.83 percent, a 26.42-percent annual compounded rate of change) and the input share of crops in the all-items CPI was higher, though still relatively modest (1.15 percent). During this subperiod, the increase in the all-items CPI was 6.80 percent; it would have been 6.19 percent had crop prices remained constant. From 2007 to 2008, almost 9 percent of the increase in the all-items CPI can be attributed to the increase in crop prices, whereas crop price increases accounted for less than 4 percent of the increase in the overall 2003–2008 period.

As one would expect, the impact of the increases in commodity crop prices on the core CPI, defined as the CPI

Table 1. Impact of price changes in crops on selected CPI categories

CPI	Average crop input shares		CPI price change		CPI price change had crop prices remained constant		Impact of crop price changes on CPI

NOTE: Last column uses calculated values; percent changes in previous columns are rounded to two decimal places.

for all items less food and energy, was much smaller because input shares were lower, averaging just 0.34 percent from 2003 to 2008 and 0.35 percent from 2007 to 2008. In the years 2003–2008, the impact of crop prices on core inflation was quite low, 13.19 percent, and it would have been only slightly lower, 12.96 percent, without the contribution from rising crop prices. Even when crop prices soared in 2007–2008, the core CPI was only slightly higher than it would have been if crop prices had remained constant (4.68 percent as opposed to 4.49 percent).

Although broad measures of price change were minimally affected by crop price movements, the runup in crop prices substantially affected the CPI for food and beverages, as the input share of crops in food and beverages, averaging 5.60 percent from 2003 to 2008, was much higher than both the share in the core CPI and the share in the all-items CPI. During this period, the CPI for food and beverages was 21.19 percent; it would have been just 17.11 percent had crop prices remained constant. Higher crop prices therefore accounted for nearly 20 percent of the total increase in the food and beverages index from 2003 to 2008. In the 2007–2008 subperiod, the impact was even stronger: the CPI for food and beverages was 9.49 percent, whereas it would have been only 6.22 percent had crop prices remained constant. The impact of rising crop prices thus accounted for nearly 35 percent of the

increase in the food and beverages component of the CPI from 2007 to 2008.

Animal slaughter and processing. As seen in chart 2, from December 2001 to December 2008 the PPI for animal slaughter and processing fluctuated, although the price trend was increasing over the period. U.S. livestock and poultry production is based predominantly on a system of grain-fed animals. Even though increased feed (grain) prices contributed to the volatility in the PPI for animal slaughter and processing from 2006 to 2008,¹² yearly average prices did not change substantially. The major upward shift in prices occurred in 2003 and 2004.

A decline in beef production, increases in demand, and the discovery of the disease bovine spongiform encephalitis (BSE), the market reaction to which limited supply in the United States, all contributed to higher beef and cattle prices through much of 2003. The higher beef and cattle prices then spurred demand for other meat items, such as pork and poultry.¹³ Although animal slaughter and processing prices dropped precipitously in late 2003 with the discovery of BSE in the United States, by mid-2004 prices had mostly recovered. A deadly bout of avian flu in Asia also contributed to the increase in animal slaughter and processing prices.

Despite strong increases in animal slaughter and proc-

Chart 2. Producer Price Index for animal slaughter and processing

essing prices in 2003–2004 and continued volatility in prices through 2008, their impact on consumer prices was limited. As shown in table 2, animal slaughter and processing price movements did not have a large impact on broad measures of CPI price change. In 2003–2008, the input share of animal slaughter and processing in the all-items CPI, while higher than the 1.05 percent for crops, was still fairly low, averaging 1.33 percent. The increase in animal slaughter and processing prices (26.26 percent, a 5.03-percent annual compounded rate of change) was also much lower than the increase in crop prices. Consequently, animal slaughter and processing prices had a minimal impact on the all-items index. Had animal slaughter and processing prices remained constant, the change in the all-items index would have been 19.37 percent, compared with the actual change of 19.70 percent. Rising animal slaughter and processing prices therefore accounted for only 1.68 percent of the change in the all-items CPI from 2003 to 2008. The impact was stronger in 2003–2004 because animal slaughter and processing price changes were greater (18.42 percent, an 8.82-percent annual compounded rate of change) and the input share of animal slaughter and processing in the all-items index was higher, but still relatively modest (1.36 percent).

During the 2-year span, the all-items CPI rose 5.02 percent, whereas it would have risen 4.78 percent had animal slaughter and processing prices remained constant. Therefore, the increase in commodity prices accounted for 4.78 percent of the change in the all-items CPI.

As regards the core CPI, the impact of increases in animal slaughter and processing prices was much smaller. In 2003–2008, the change in the core index was 13.19 percent, and it would have been only marginally lower, 13.12 percent, without the contribution from rising animal slaughter and processing prices. Even in the 2003–2004 subperiod, when prices rose more substantially, the core index was only slightly higher than it would have been had animal slaughter and processing prices remained constant (3.25 percent compared with 3.20 percent).

Although animal slaughter and processing price movements affected broad CPI measures only minimally, they had a substantial impact on the CPI for food and beverages because of their high input share (more than 8 percent for both 2003–2008 and the 2003–2004 subperiod). From 2003 to 2008, the food and beverages index increased 21.19 percent; without the contribution from higher animal slaughter and processing prices, it would have increased only 19.19 percent. Higher animal slaughter and

Table 2. Impact of price changes in animal slaughter and processing on selected CPI categories

Animal slaughter and processing PPI price change	18.42	26.26
Annual compounded rate of change	8.82	5.03

NOTE: Last column uses calculated values; percent changes in previous columns are rounded to two decimal places.

processing prices therefore accounted for 9.43 percent of the total change in the food and beverages index in that period. In 2003–2004, the impact was even stronger: the food and beverages index increased 5.59 percent, whereas the change would have been only 4.14 percent had animal slaughter and processing prices remained constant. In sum, animal slaughter and processing prices accounted for more than one-quarter of the food and beverages price change during the subperiod.

Dairy. The dairy PPI was derived from the industry-based PPI for dairy product manufacturing.¹⁴ As seen in chart 3, dairy prices have historically been less volatile because of government price support programs and a market loss payment system. In recent years, however, a number of factors and events led to price uncertainty and volatility in the dairy product-manufacturing industry: total milk production, which is influenced by both the number of milk cows and the amount of milk per cow; commercial stocks; international trade; and changes to the regulation of dairy products.

From 2000 to 2006, dairy prices were relatively stable, although the industry did see a sharp spike in 2004 due to a rapid decline in milk cow numbers following a ban on imported animals from Canada after the discovery of BSE earlier in the year. Dairy prices began to increase steadily

from mid-2006 through mid-2007 and remained high through mid-2008. The upward price shift was driven by strong demand and tight global supplies. Low stocks in the European Union, lower milk production because of droughts in Australia, New Zealand, and the United States, and strong demand (particularly from China) all contributed to the price increases.¹⁵

As with crops and animal slaughter and processing, rising dairy prices did not strongly influence the all-items or core CPI. Table 3 shows that the impact of dairy price movements on inflation was smaller than that attributable to those two commodities, primarily because of their higher input share. In 2003–2008, the input share of dairy in the all-items CPI averaged 0.65 percent while dairy prices rose 34.20 percent (a 5.03-percent annual compounded rate of change). Had dairy prices been flat over the period, the increase in the all-items CPI would have been 19.49 percent, compared with the actual value of 19.70 percent. Therefore, rising dairy prices accounted for a little more than 1 percent of the change in the all-items index during 2003–2008. In 2007, when dairy prices rose at their highest rate, their impact on the all-items CPI was still minimal: despite a 19.11-percent rise in dairy prices, the change in the all-items index was only about 0.1 percentage point higher than it would have been had dairy prices remained constant (2.73 percent as opposed to 2.85 percent).

Chart 3. Producer Price Index for dairy

The impact of the increases in commodity dairy prices on the core CPI was nearly nonexistent as the input share of dairy in the core CPI was just 0.14, on average, both in 2003–2008 and in 2007. From 2003 to 2008, the increase in the core index was 13.19 percent, and it would have been only marginally lower, 13.15 percent, without the contribution from rising dairy prices. In 2007, despite the 19.11-percent increase in dairy prices, the core CPI was still only marginally higher than it would have been had dairy prices remained constant (2.33 percent compared with 2.30 percent).

Increases in dairy prices did substantially affect the CPI for food and beverages through the higher input share of dairy (3.90 percent from 2003 to 2008, 3.83 percent in 2007) in food and beverages, although the impact was largest in 2007. In 2003–2008, the change in the CPI for food and beverages was 21.19 percent, whereas it would have been 19.95 percent, a relatively modest impact, had dairy prices remained constant. In 2007, however, the food and beverages index rose 3.91 percent; had dairy prices remained constant that year, the index would have risen only 3.20 percent. Rising dairy prices therefore accounted for nearly 18 percent of food and beverages inflation in 2007.

Oil and gas. The oil and gas PPI was calculated by aggregating indexes for natural gas, crude petroleum (domestic production), and liquefied petroleum gas. As seen in chart 4, crude oil and natural gas prices have historically been quite volatile. The depletion of finite resources, changes in exchange rates, policies of the Organization of the Petroleum Exporting Countries (OPEC), political and environmental shocks, commodity speculation, and changes in demand have all influenced oil and gas price movements in the past. Between 2001 and 2008, a number of these factors contributed to large price spikes in 2003, 2005, and 2008.

The increase in natural gas and oil prices in 2003 was due largely to a Venezuelan oil strike in late 2002 that reduced crude oil production and led to an increase in the world price of the commodity. According to the U.S. Department of Energy, the United States received more than half of Venezuela's crude exports at the time and replacing the lost volumes proved difficult.¹⁶ High prices at the end of 2005 were due to shocks to oil and natural gas infrastructure caused by Hurricanes Katrina and Rita hitting the Gulf of Mexico.¹⁷ All oil and natural gas production in the Gulf was shut in, import terminals were closed, and several pipelines and refineries were inoperable.¹⁸

Table 3. Impact of price changes in dairy on selected CPI categories

Dairy PPI price change	19.11	34.20
Annual compounded rate of change	19.11	5.03

NOTE: Last column uses calculated values; percent changes in previous columns are rounded to two decimal places.

The increase in crude oil and natural gas prices that culminated in record-high prices in mid-2008 was driven by strong demand from Europe, Latin America, the Middle East, and Asia, as well as the declining value of the dollar. After peaking in midyear, prices decreased rapidly through the rest of the calendar year. Between lessening demand for crude oil and weakened economies in the United States and Europe, the global market for crude oil declined. Concerns about slowing global demand affected futures traders and OPEC alike, depressing prices further.

In contrast to crops, animal slaughter, and dairy, rising oil and gas prices had a large impact on overall consumer price inflation. Movements in oil and gas prices had a pronounced effect on the percent change in the all-items CPI through both the magnitude of the increases in oil and gas commodity prices and the substantially higher input share of oil and gas in the all-items index. As table 4 shows, from 2003 through 2008 oil and gas prices increased 232.25 percent (a 22.16-percent annual rate) and the average input share was 3.88 percent. Over that period, the percent change in the all-items CPI was 19.70 percent; had oil and gas prices remained unchanged, it would have been 14.55 percent. Rising oil and gas prices therefore accounted for more than 25 percent of the percent change in the all-items CPI from 2003 to 2008. In 2008,¹⁹ the impact was even more pronounced because of the large price

increase (30.09 percent) and the high input share (4.78 percent). In that year, the percent change in the CPI for all items was 3.84 percent, whereas it would have been 2.40 percent had oil and gas prices remained constant. Higher oil and gas prices therefore accounted for 37.48 percent of the percent change in the all-items CPI in 2008. Rising oil and gas prices accounted for a substantial amount of the inflation both over the entire period from 2003 to 2008 and in 2008. However, the overall rate of inflation was still quite modest relative to the magnitude of the price increases in oil and gas, demonstrating that even large movements in oil and gas prices do not necessarily lead to extremely high inflation.

Price movements in oil and gas also affected core inflation substantially. The input share of oil and gas in the core CPI, though smaller than that for the all-items CPI, averaged 2.54 percent from 2003 to 2008 and 3.05 percent in 2008. Core inflation was 13.19 percent over the 2003–2008 period and would have been 9.77 percent without the contribution from higher oil and gas prices. As with the all-items CPI, higher oil and gas prices therefore accounted for 25.93 percent of core inflation during the period. In 2008, core inflation was 2.30 percent, and it would have been only 1.38 percent had oil and gas prices not increased. In that year, higher oil and gas prices therefore accounted for 39.92 percent of core inflation, similar

Chart 4. Producer Price Index for oil and gas

to the impact that increasing gas and oil prices had on the percent change in the all-items CPI. The high percentage of both the all-items CPI and core inflation accounted for by oil and gas prices indicates the importance of oil and gas prices to a broad range of goods and services.

Many different CPI categories were affected considerably by rising oil and gas prices, but the three categories affected most from 2003 through 2008 were transportation, motor fuels, and fuels and utilities. In analyzing the impact of higher oil and gas prices on these indexes, the fact that oil and natural gas are combined in the input–output tables and treated as one industry or commodity becomes a limitation. Crude oil and natural gas prices do not always move in a similar fashion, and some final-demand categories are more sensitive to one than the other. Most notably, large increases in crude oil prices lead to substantial increases in the CPI for transportation and motor fuels whereas natural gas price movements are the more dominant factor in fuels and utilities. Despite this limitation, useful information can still be gleaned from examining the impact of combined oil and gas prices on these subindexes.

Motor fuel and transportation. The input share of oil and

gas in motor fuel averaged 43.64 percent from 2003 to 2008. During this period, the percent change in the CPI for motor fuel was 139.82, whereas it would have been only 69.02 percent without the contribution from higher oil and gas prices. Oil and gas price movements therefore accounted for more than half (50.63 percent) of the increase in the CPI for motor fuel during the 2003–2008 timeframe.²⁰ In 2008, the impact was even stronger: the increase in the CPI for motor fuel was 16.97 percent, whereas it would have been just 2.44 percent had oil and gas prices remained constant. Higher oil and gas prices therefore accounted for a large part of the increase in motor fuel prices in 2008.

Motor fuel is a subcategory of the broader CPI transportation index. As can be seen in table 4, almost 67 percent of the inflation in transportation from 2003 to 2008 was caused by rising oil and gas prices. Nearly all (93.69 percent) of the 5.88-percent inflation in transportation in 2008 can be attributed to increasing oil and gas prices. Although the oil and gas input share of transportation is less than that of motor fuel, crude oil prices were still the main driver for CPI transportation inflation.

Fuels and utilities. The input share of oil and gas in fuels

Table 4. Impact of price changes in oil and gas on selected CPI categories

CPI	Average oil and gas input shares		CPI price change		CPI price change had oil and gas prices remained constant		Impact of oil and gas price changes on CPI	
	2008	2003–2008	2008	2003–2008	2008	2003–2008	2008	2003–2008

Annual compounded rate of change	30.09	22.16

NOTE: Last column uses calculated values; percent changes in previous columns are rounded to two decimal places.

and utilities averaged 24.06 percent from 2003 to 2008. During this period, the percent change in the CPI for fuels and utilities was 53.25 percent, whereas it would have been only 17.14 percent without the contribution from higher oil and gas prices. Oil and gas price increases therefore accounted for more than two-thirds (67.81 percent) of the increase in fuels and utilities prices over the 2003–2008 period. In 2008, the impact was stronger: the CPI for fuels and utilities was 9.66 percent; it would have been just 1.83 percent had oil and gas prices remained constant. Higher oil and gas prices therefore accounted for 81.03 percent of the increase in prices for fuels and utilities in 2008.

THE ANALYSIS PRESENTED IN THIS ARTICLE has revealed results similar to those of Hobijn. The effect of commodity price increases was more pronounced for specific CPI categories than it was for broader CPI measures. Higher oil and gas prices substantially affected motor fuels, transportation, and fuels and utilities price changes, and increasing crop, animal slaughter and processing, and dairy prices contributed to higher prices for food and beverages. From 2003 to 2008, price increases in crops, animal slaughter and processing, and dairy accounted for slightly more than one-third²¹ of the increase in the food and beverages CPI; in subperiods when price movements in these

commodities were especially strong, the impact was even more pronounced. Crops, animal slaughter and processing, and dairy together accounted for about 7 percent of the all-items CPI price change and less than 3 percent of the core CPI price change during the 2003–2008 period. Furthermore, even the largest price movements for these commodities in a given year contributed only minimally to all-items and core inflation. From 2003 to 2008, higher oil and gas prices accounted for approximately two-thirds of the increase in transportation prices, about one-half of the increase in motor fuel prices, and roughly two-thirds of the increase in fuels and utilities prices. In 2008, the substantially higher oil and gas prices accounted for a majority of the price increase in all three indexes.

However, unlike Hobijn's account, the analysis presented here finds that oil and gas commodity price movements had a substantial impact on the all-items CPI, as well as on lower level indexes both in the longer term and in specific years. Rising oil and gas prices contributed substantially to both all-items and core CPI price changes from 2003 through 2008, accounting for approximately 26 percent of both indexes combined. During years of large price increases in oil and gas, higher prices accounted for an even greater share of the all-items and core CPIs; in 2008, higher prices accounted for nearly 40 percent of each. Whereas almost all subindexes were substantially affected

by oil and gas prices, the most heavily affected were transportation, motor fuels, and fuels and utilities.

Several factors could have contributed to the difference between Hobijn's findings and those of this analysis with regard to the impact of oil and gas commodity prices on all-items CPI inflation. Whereas Hobijn used the 2006 BEA input-output tables to compute input shares, this study has used the updated 2008 BEA input-output tables. In addition, the aggregated PPI index for oil and gas used here includes commodity data for liquefied petroleum, a PPI category that did not appear in Hobijn's oil and gas index. Lastly, the analysis presented here has used CPI data in order to analyze the effect of commodity price movements on consumer inflation, while Hobijn used PCE data

to calculate this pass-through.

In sum, crops, animal slaughter and processing, and dairy price movements had a limited impact on CPI inflation while the impact of oil and gas commodity price movements was much larger. From 2003 through 2008, crop prices rose by 83 percent, animal slaughter prices grew by 26 percent, dairy prices increased by 34 percent, and oil and gas prices shot up by 230 percent. Despite all this growth, CPI inflation was just 19.7 percent over the same period. Thus, although crop, animal slaughter and processing, dairy, and oil and gas commodity prices are important contributors to consumer price inflation, even large increases in the prices of these commodities do not necessarily lead to excessively high rates of inflation. □

¹¹ Let $CPI(i, j)$ = annual average CPI value for category j in year i , $PPI(i, j)$ = annual average PPI value for category j in year i , and $share(i, j)$ = input share for year i for category j . Then the formulas for columns 2, 3, and 4 are as follows:

$$\text{Column 2: } \prod_{i=1}^N \left(\frac{CPI(i, j)}{CPI(i-1, j)} - 1 \right) \times 100$$

$$\text{Column 3: } [\text{Column 2}] \times [100\% - [\text{Column 4}]]$$

$$\text{Column 4: } \prod_{i=1}^N \left[\text{share}(i, j) \times \left(\frac{PPI(i, j)}{PPI(i-1, j)} - 1 \right) + 1 \right] - 1 \times 100 / [\text{Column 2}]$$

¹² Increased production costs (due to higher feed prices) led farmers to increase slaughter rates, putting downward pressure on prices in the short term with the increased supply to market. The upward and downward price movements from 2006 to 2008 reflected which of these two factors (higher feed prices or increased slaughter rates) was dominant in the short term.

¹³ Monthly reports on various aspects of agriculture appear on the website of the Economic Research Service of the U.S. Department of Agriculture, www.ers.usda.gov. ¹⁸ For safety reasons, oil and gas companies will "shut in" production from offshore platforms that are expected to be in the path of a hurricane. The platforms are abandoned until the storm passes.

¹⁹ As discussed earlier, there were three major movements in oil and natural gas producer prices from 2001 to 2008: in 2003, 2005, and 2008. In all 3 years, oil and gas prices were up by more than 30 percent. The year 2008 is chosen as the subperiod of interest because the input share was the highest in that year, causing the price movement in 2008 to have the largest impact.

²⁰ Major inputs into fuel prices are oil and gas extraction, petroleum and coal products manufacturing, and wholesale and retail margins. A plausible explanation for the fact that oil prices account for only about 50 percent of fuel price increases is that refining (petroleum and coal products manufacturing) costs went up. Also, in more recent years transportation costs have been affected by volatility in ethanol prices.

²¹ The contribution of one-third was arrived at by adding the various impacts of the commodity price changes on the CPI (i.e., 19.26 for crops, 9.43 for animal slaughter and processing, and 5.86 for dairy, totaling 34.55 percent).

APPENDIX A: Detailed methodology

To determine the impact of commodity price movements on the price of final consumer goods, the input share for each commodity needs to be calculated. The input share quantifies the importance of the different commodities for the production of the final goods. To calculate input shares for the commodities of interest in this article, this appendix follows a method described by Hobijn.¹ The method utilizes a modified Leontief model, expressed in linear form as $\mathbf{r} = \mathbf{A}\mathbf{r} + \mathbf{b}$.

Solved for \mathbf{r} , the equation can be written as $\mathbf{r} = (\mathbf{I}_n - \mathbf{A})^{-1}\mathbf{b}$. In matrix form, this equation can also be expressed as $\mathbf{r} = (\mathbf{I}_n - \mathbf{A})^{-1}\mathbf{b}$, in which \mathbf{r} represents the input share, vector \mathbf{b} represents the proportions of each commodity in final-demand categories, \mathbf{I}_n is the 202×202 identity matrix, and \mathbf{A} is a commodity–commodity direct requirements (CCDR) matrix, a 202×202 matrix whose (i,j) th element is the amount, in dollars, of commodity i directly required to produce \$1 of commodity j for final use.² The matrix that results from taking the inverse of the difference of the identity matrix and the CCDR matrix $[(\mathbf{I}_n - \mathbf{A})^{-1}]$ is an important component of the methodology used here and is known as the commodity–commodity total requirements (CCTR) matrix, a 202×202 matrix whose (i,j) th element is the production required, both directly and indirectly, of commodity i per dollar of delivery to final use of commodity j . Once the CCTR matrix and the proportions of final demand for each commodity are calculated, the input shares \mathbf{r} of the commodities in the final-demand category may be found by taking the cross product of the two: $\mathbf{r} = \text{CCTR} \times \mathbf{b}$.

Note that several steps were required to calculate the CCTR matrix. The process begins with the make and use tables compiled by Carl Chentrens for the Bureau of Labor Statistics.³ The make table is a 202×202 matrix whose (i,j) th element is the value of commodity i 's output by industry j in a given year, and the use table is a 202×202 matrix whose (i,j) th element is the value of commodity i used in industry j (e.g., the value of crops used in animal production).

The make and use tables are then used to calculate the CCDR matrix.⁴ One adjustment was made to this matrix (similar to Hobijn's method): the columns for the commodities of interest (crops, animal slaughter and processing, dairy, and oil and gas) were zeroed out. This adjustment must occur because the prices for these commodities are gross output prices and already reflect the inputs used in their production. However, as Hobijn explains, because of

the adjustment, the input shares of the four commodities examined do not include the input share of each in the production of the other.⁵ Once this adjusted CCDR is created, it is subtracted from a 202×202 identity matrix and the inverse of the resulting matrix is taken, yielding the CCTR matrix.

After the CCTR matrix is obtained, the values for vector \mathbf{b} , are calculated. These values represent the share of each commodity in the final-demand categories of interest. Calculating the values of \mathbf{b} starts with the final-demand table from the input–output tables. The final-demand table is a 202×203 matrix whose (i,j) th element is the value of commodity i used to meet the final consumer demand for category j (e.g., the value of printing and related support activities in the category of magazines, newspapers, and sheet music). Two steps are necessary to turn the final-demand tables into the required vectors. First, the amounts listed in the final-demand table need to be converted from purchaser's values to producer's values to make them comparable to the amounts shown in the make and use tables. The purchaser's value is equal to the producer's value plus wholesale and retail trade margins and costs relating to the transportation of the good (by rail, air, water, truck, or pipeline) to the point of purchase. The final-demand table includes columns indicating the amount of the purchaser's value that is due to margin and transportation costs. These given margin and transportation amounts are redistributed back into the commodities to convert the values to producer's prices. Once the values in the final-demand table are adjusted from purchaser's to producer's values, each value in the table is divided by the sum of the entries in its column. Because the final-demand tables detail the amount of each commodity used to meet final consumer demand for a category, dividing by the column totals in this manner gives the proportion of final demand accounted for by each commodity.

At first glance, it may seem that these columns represent the final input shares in which we are interested. However, the final-demand table indicates only how much of each commodity *that is available for final use* is needed to produce each item. The table does not take into account how much of each different commodity is required to make available a dollar's worth of a commodity for final use. The CCTR matrix is needed because it quantifies the interindustry linkages of the different commodities. Multiplying the columns representing the share of each com-

APPENDIX A: Continued—Detailed methodology

modity in the final-demand categories of interest by the CCTR yields the final input shares for each commodity in

the production of the final goods that take into account all inputs of the commodities along the way.

APPENDIX B: Glossary

Commodity–commodity direct requirements (CCDR) matrix A 202×202 matrix whose (i,j) th element is the amount, in dollars, of commodity i directly required to produce \$1 of commodity j for final use.

Commodity–commodity total requirements (CCTR) matrix A 202×202 matrix whose (i,j) th element is the production required, both directly and indirectly, of commodity i per dollar of delivery to final use of commodity j . Equal to the inverse of the difference of the identity matrix and the CCDR: $CCTR = (I_n - CCDR)^{-1}$.

Final-demand table A 202×203 matrix whose (i,j) th element is the value of commodity i used to meet the final consumer demand for category j .

Input–output tables A means of presenting a detailed analysis of the process of production and the use of goods (products) and services and the income generated in that process. The tables are either (a) make and use tables or (b) symmetric input–output tables.¹ The tables compiled by Chentrens and used in this article are make and use tables.

Input share A measure of the importance of a com-

modity for the production of final goods.

Leontief model A standard model, given by $\mathbf{x} = (\mathbf{I}_n - \mathbf{A})^{-1}\mathbf{y}$, that relates final demand \mathbf{y} to total output \mathbf{x} through the interindustry linkages represented by the total requirements matrix $(\mathbf{I}_n - \mathbf{A})^{-1}$. Widely used in economic impact analysis to model the changes in total output that are needed to satisfy a change in final demand.

Make table A 202×202 matrix whose (i,j) th element is the value of commodity j 's output by industry i in a given year.

Producer's value The value that a producer receives for a good. (e.g., the amount a farmer receives for his or her crops).

Purchaser's value The sum of producer's value and wholesale and retail trade margins and costs relating to the transportation of the good (by rail, air, water, truck, or pipeline) to the point of purchase.

Use table A 202×202 matrix whose (i,j) th element is the value of commodity i used in industry j (e.g., the value of crops used in animal production).

No longer tax exempt: income tax calculation in the Consumer Expenditure Survey

BLS has developed an experimental federal income tax calculator that estimates taxes for Consumer Expenditure Survey participants to help address high nonresponse rates, unreliable reporting, and time-frame ambiguity; this calculator could improve the quality of the aftertax income data in the survey

Aylin Kumcu

The primary aim of the Consumer Expenditure Survey (CE) is to record the expenditure behavior of American households. The CE program conducts two surveys that collect data on the expenditures, income, and characteristics of consumer units: the Diary Survey and the Quarterly Interview Survey. The Bureau of Labor Statistics (BLS) publishes the results of these surveys at the aggregate level, and the microdata are studied by a wide variety of users. One of the main users of CE data is the Consumer Price Index, which employs the data to update the cost weights for its market basket of goods and to calculate the relative importance of these aggregate goods. CE data also are widely used by other government agencies, academia, and members of the public for research, policymaking, and other purposes, because the CE survey is one of the sole sources of high-quality, sample-based U.S. data that links expenditures and income at the household level.¹

While the survey's primary objective is to collect information on expenditures, it is also important that it provide accurate data

on household income. However, some respondents may consider the income questions sensitive in nature, resulting in high nonresponse rates for some questions. To address this issue, in 2005 the CE began to include imputed income in its 2004 published tables and 2004 public use microdata. However, the CE has not yet implemented a method for estimating or imputing aftertax income. Considering the issues related to the quality of reported tax information in the CE, this study explores the possibility of calculating household tax liability using other highly reliable information from the survey.

The federal income tax predicament

There are two main issues related to the income taxes reported in the CE. First is the question of high nonresponse rates and the quality of reported data. Many individuals surveyed in the CE do not respond to the tax questions. For those who do respond, it is unclear how accurate their responses are. Although some respondents may report correct taxes around the time they file their income tax return, it is not possible to determine how accurate their memory is without knowing whether they re-

Aylin Kumcu is currently an agricultural economist at the U.S. Department of Agriculture, Economic Research Service and formerly worked at the Bureau of Labor Statistics. The views expressed do not necessarily represent those of USDA. Email: akumcu@ers.usda.gov.

ferred to their records or documents. Second, the tax year to which the tax variables refer changes throughout the interview year because of the CE survey design and the wording of its tax-related questions.

The CE program currently estimates total income taxes using other variables because it does not measure them directly. Total tax paid is the sum of taxes withheld from the respondent's paycheck and additional tax paid, minus tax refunds. More specifically, total tax paid includes the following²:

- Annual federal income tax deducted from salary³
- Annual state and local income tax deducted from salary⁴
- Federal tax paid in addition to that withheld from paycheck in the past 12 months
- State and local tax paid in addition to that withheld from earnings in the past 12 months
- Personal property tax paid in the past 12 months
- Other taxes paid in the past 12 months which were not reported elsewhere

These refunds are then deducted in calculating total income tax:

- Amount of refund received from federal income tax in the past 12 months
- Amount of refund received from state and local income tax in the past 12 months
- Amount of other refunds received, including any other tax refunds, during past 12 months

Total federal tax is comprised of the *federal tax* elements from above and can be represented in the following way:

$$\text{Total CE federal tax paid} = \text{Tax deducted} + \text{Tax paid} - \text{Tax refund} \quad (1)$$

(Exhibit 1 depicts how these variables would be filled on the 1040 Individual Tax Form.) This estimate aims to include the earned income tax credit (EITC) and the additional child tax credit, which are given as refunds and tend to be an important part of individuals' income tax liability, but the CE cannot explicitly verify these two credits are accurately reported.

By calculating total tax paid in this manner, the CE attempts to capture what a consumer unit (CU)⁵ actually owes the Internal Revenue Service (IRS) in order to determine aftertax income. The CE estimates after-tax income as follows:

$$\text{Income after tax} = \text{Income before tax} - \text{Total tax paid} \quad (2)$$

Income before tax is the total amount of income, including the dollar value of Supplemental Nutrition Assistance Program benefits (formerly called food stamps) and other transfers, before any taxes are paid. Total tax paid is the total amount of tax paid as described above. Aftertax income is the total amount of income after all taxes are paid. In other words, it is the income a CU has at its disposal to spend on goods and services. If total tax is zero because a respondent does not answer or does not know, aftertax income exactly equals beforetax income. In fact, this is the case for nearly 40 percent of the Quarterly Interview Survey sample in the third quarter of 2005.

The CE program's estimate of total tax is likely to be inaccurate for a large portion of the survey sample because of high rates of nonresponse or incorrect responses and ambiguity surrounding the time frame to which the tax variables refer. The following tabulation for the third quarter of 2005 shows a large majority of individuals report that taxes were deducted from pay:

Interviewees' response to the question, "Was federal tax withheld from last paycheck?"

<i>Taxes deducted?</i>	<i>Number of individuals</i>	<i>Percent</i>
Yes	8,409	87
No	838	9
Refuse or don't know.....	415	4

However, approximately two-thirds of individuals do not report how much federal tax was withheld from their last paycheck even when they report that tax was indeed withheld. As shown below, only 32 percent of individuals who reported federal tax was deducted from their wages or salary actually reported nonzero tax withholdings in the third quarter of 2005:

Amount of tax withheld from paycheck of individuals who reported that federal tax was withheld

<i>Amount deducted</i>	<i>Number of individuals</i>	<i>Percent</i>
Zero.....	5,740	68
Greater than zero.....	2,669	32

The next tabulation shows that this percentage is slightly greater at the CU level. Among the consumer units where at least one member reported that federal tax was withheld, 37.5 percent actually reported a nonzero value for total tax withholdings:

Amount of tax withheld from paycheck for consumer units in which at least one member reported that federal tax was withheld

<i>Amount deducted</i>	<i>Number of households</i>	<i>Percent</i>
Zero.....	3,340	62.5
Greater than zero.....	2,004	37.5

NOTE: The variables in bold are values calculated by the tax calculator. The variables in italics are reported values in the Consumer Expenditure Survey. SOURCE: U.S. Bureau of Labor Statistics, using Internal Revenue Service tax form.

The inconsistency presented by such a large portion of the interviewees' responses suggests nonresponse rates are sufficiently high to cause imprecise values for total federal tax at the micro and aggregate levels.

A second factor affecting the accuracy of the estimates is uncertainty surrounding the tax year to which the variables that are used to calculate income tax in the CE refer. Because the survey asks if taxes were paid or a refund was received in the past 12 months, there are three possible scenarios regarding to which tax year the taxes and refunds refer:⁶

- A. The tax paid and refund received are from the previous tax year if the CU has not filed taxes yet; that is, the interview took place in the first quarter of the year.
- B. They are from the current tax year if the CU has filed taxes and received a refund for the current year; that is, the interview took place in the second, third, or fourth quarter.

- C. They are from both the previous and current tax year, which could theoretically happen in any quarter; for example, the interview took place in May 2005 and the CU received two refunds in the past 12 months, which is possible if the CU just received a refund for the current tax year (2005) but had not received a refund for the previous year (2004) until June 2004.

It is unknown which scenario occurs given the current CE questionnaire. However, it is most likely that interviews which take place in the first quarter lead to scenario A, though a very small portion of the population will have already filed their taxes and received their refund. In the case of scenario A, the CE will underestimate tax liability because it assumes tax from last year will exactly equal the tax for this year, which is probably not the case. It is likely that interviews which take place in the third and fourth quarters lead to scenario B, though again a very small portion of respondents may have filed their taxes very late last year but early or on time this year, leading to scenario

C. In the case of scenario B, the CE will accurately reflect taxes. In the case of scenario C, the CE will overestimate taxes because the reported tax will reflect 2 years of taxes. Interviews which take place in the second quarter could reflect any of the three scenarios.

The CE also makes some important assumptions in using these variables to estimate aftertax income. (Recall equation (2) for total tax paid.) First, all of the income and tax questions refer to the previous 12 months, which means the CE assumes that the values for the last 12 months will be the same for the 12 months of the current tax year. (This situation is further confounded for CUs in their third and fourth interviews, whose income and tax values refer to an even earlier time frame. See endnote 6.) Second, the amount of tax reported as being withheld from pay is based on the amount of tax withheld from the latest paycheck. This assumes the rate of tax withheld from the latest paycheck will be the same for each paycheck that year. This assumption will be inaccurate for individuals whose paychecks vary enough throughout the year that their average tax rate is not consistent from one paycheck to another. These issues also apply to the CE's state and local tax variables.

Although it is not a simple matter to circumvent the fact that CE income and tax variables refer to the previous 12 months, the other points previously discussed regarding federal income tax can be readily addressed. We can calculate federal income tax directly using demographic characteristics and reported or imputed income and expenditures, all of which are highly reliable. This calculation avoids issues resulting from nonresponse or incorrect information and ambiguity of timeframe.

The tax man: a potential solution

The tax calculator developed by BLS approximates federal income tax using various sources of income, expenditures, and CU characteristics reported by interviewees in the CE survey. The resulting estimates avoid relying on respondents who may not recall their tax liability or who refuse to answer tax questions, and the estimates overcome assumptions made because of the format of the CE questionnaire. The tax calculator uses the 1040 Individual Income Tax Return Form and supplementary forms and worksheets to calculate taxes as if respondents were filing their tax returns using the information reported to the CE. The main tax variable of interest for this report is the total federal income tax owed to the IRS including the earned income tax credit (EITC) and

the additional child tax credit:

$$\text{Total tax calculator tax paid} = \text{Total tax} - \text{EITC} - \text{Additional child tax credit} \quad (3)$$

Total tax is line 63 of the 1040 form, total tax before subtracting any payments. The EITC is line 66a, and the additional child tax credit is line 68. (See exhibit 1, 1040 Individual Income Tax Return Form 2006.) This is the closest possible approximation that can be made to a CU's total tax liability for the purpose of calculating aftertax income.

The tax calculator calculates taxes for tax units (TUs)—that is, groups of individuals who file together—rather than for consumer units, groups of individuals who live together and share certain expenses. The following tabulation shows the relationship between consumer units and tax units:

<i>Number of tax units per consumer unit</i>	<i>Percent of sample</i>
1	76
2	18
3 or more	6

The tax calculator includes the largest sources of income for a majority of the population, deductions for educational expenses, contributions to retirement accounts, and the standard and itemized deductions, as well as certain credits for which CE data are available. (See exhibit 2, which shows ingredients of the tax calculator.) Because of data constraints, the tax calculator does not accurately calculate total tax owed by the self-employed; the self-employment tax is included but business expenses are not deducted. The mean total income for income reporters was \$64,440.28, the mean total tax paid was \$2,354.31, and the mean average tax rate was 0.7 percent. (See table 1.)

The tax calculator must make some basic assumptions for simplification and to circumvent obstacles in the data. First, the tax calculator assumes everyone in the survey files the 1040 Individual Income Tax Return Form, everyone in the sample is a U.S. citizen, no one is clergy, and no one is blind. In addition, some simplifications are made when distinguishing between tax units and consumer units. There are three options for filing status:

1. Single: Any tax unit that contains only one “unmarried” adult, including widow(er)s and interviewees who report they are married but do not reside with their spouse⁷

2. Married, filing jointly: Any tax unit in which the two spouses reside in the same home and are married to each other
3. Head of household: Any tax unit which contains dependents and an adult who is “unmarried,” including interviewees who report they are married but do not reside with their spouse, and also widow(er)s

1. Any person who is less than 19 years old
2. Children who are less than 25 years old, are in college, and do not work full time
3. Relatives who are any age and disabled
4. Relatives who earn no more than the maximum income to be considered a dependent

Taxes are also calculated for dependents who earn enough income that they must file separately.

In the third quarter of 2005, the proportion of survey respondents in each filing status was as follows:

<i>Filing status</i>	<i>Filing status of tax units</i>	<i>Percent of sample</i>
Single.....		51
Married, filing jointly		39
Head of household		8
Dependent, filing separately.....		2

There are four kinds of dependents:

Some additional assumptions are made to calculate income, adjusted gross income (AGI), itemized deductions, and tax credits. The tax calculator assumes the income and tax reported by the interviewee refer to the previous tax year even though the questionnaire refers to “the previous 12 months.” Capital gains and losses are not included as a source of income, and dividends are taxed at the same rate as all other income. Refunds from state and local taxes paid in the previous tax year (previous 12 months) are assumed to be taxable refunds for TUs that have a mortgage in the current period, because it is likely these households

Table 1. Mean total income, federal income tax, and average tax rate for Consumer Expenditure Survey tax reporters, by type of consumer unit

Type of consumer unit	Total income ¹	Total federal income tax ²	Average tax rate ³	N
All consumer units	\$64,440.28	\$2,354.31	0.7	1,876
Single, no children	38,889.55	1,833.77	4.3	584
Married, with or without children	91,653.79	3,400.65	2.7	855
Single parent, with children	32,168.51	37.29	-21.9	171
Other consumer units	57,521.74	1,736.01	1.1	266

¹ Total income refers to income for tax purposes only; it does not include workers' compensation or veterans' benefits, public assistance or welfare income, or the dollar value of food stamps.

² Federal income tax is the sum of the federal income tax values, including refunds, as described in equation (1).

³ Average tax rate is federal income tax divided by total income.

NOTE: Data are from the Consumer Expenditure third quarter 2005 quarterly interview for consumer units that are in the second or fifth interview and report a valid response to each of the questions used to calculate total federal income tax. The data are weighted to be representative of the U.S. population at the aggregate level.

SOURCE: U.S. Bureau of Labor Statistics.

had a mortgage last year and itemized their deductions. Finally, limits are not placed on income losses, such as losses from self-employment or rental real estate.

For AGI, the tax calculator includes contributions made to retirement plans, half of the self-employment tax, and the deduction for tuition fees. It also assumes self-employed individuals have Simplified Employee Pension plans, and all other individuals have individual retirement accounts (IRAs). The tax calculator assumes everyone who has tuition expenditures will take the tuition deduction rather than the tuition credit, because the deduction leads to less tax owed, and because the CE cannot determine whether the student is eligible for the credit. A simplifying assumption is made for dependents who file separately: the tax calculator gives these dependents the deduction, although in reality the tax head who claims them takes the deduction. The aggregate effect of this assumption is minimal because the final tax is calculated at the consumer unit level.⁸

The assumptions made regarding itemized deductions are as follows: First, mortgage interest paid this quarter is consistent across the entire tax year. Second, all contributions to educational institutions, religious organizations, charities, and all other organizations (not including political organizations) are deductible, as outlined in the 1040 instructions. Third, no deductions are taken for casualty and theft losses, job expenses, or miscellaneous deductions because the CE does not have this information. Finally, health expenditures reported to the CE are assumed to reflect annual expenditures. The questionnaire asks for medical expenditures from the previous quarter, and thus includes only 3 months of health insurance pre-

miums, prescription drugs, and doctors' visits or hospital bills. This assumption will be inaccurate for CUs that cannot deduct insurance premiums (because they are paid with before-tax dollars) and CUs that can deduct all premiums incurred over the tax year.⁹ It will also be inaccurate for CUs that make the same expenditures for prescription drugs or doctors' and hospital visits during each quarter of the tax year. However, only a small portion of the U.S. population takes the itemized deduction because of their high medical expenditures, and therefore this simplifying assumption was made.

The credits computed by the tax calculator include the credit for child and dependent care expenses, the credit for the elderly or disabled, the child tax credit, and the earned income tax credit. The credit for child and dependent care expenses does not require us to make any assumptions for the majority of tax units. For CUs with multiple tax units, each of which has dependents, the tax calculator will overestimate childcare expenses because the tax calculator does not divide expenses among dependents in different TUs. The credit for the elderly or disabled requires the tax calculator to make two assumptions: First, individuals will only take the credit if their reason for not working is that they are disabled. People are eligible to take the credit if they are older than age 65 or are "retired on permanent and total disability."¹⁰ However, the CE groups reasons for not working into a single category that includes retired, taking care of the home and/or family, student, ill/disabled/unable to work, unable to find work, or doing something else.¹¹ Thus interviewees who retired on disability could respond that they are not working because they retired or because they are disabled, but

not both, and we will underestimate their credits. Second, the tax calculator must assume that all disability income is nontaxable and that all pensions are taxable because the CE does not distinguish between taxable and nontaxable income. This will cause the tax calculator to inaccurately estimate the credit for some TUs, such as those that earn nontaxable veteran's pensions. No additional assumptions are required for the child tax credit or the EITC.

The tax calculator, once created and tuned to the CE data needs, requires minimal maintenance. Annual updates must be made for new tax rates and thresholds, as well as for changes to the tax code. The tax calculator is designed in such a way that updating and incorporating the new tax rates and thresholds would require little work. In addition, the tax rates, thresholds, and changes to the code are all available in *Instructions for Form 1040, U.S. Individual Income Tax*, published by the IRS and available on the IRS website. All major changes to the tax code are outlined in the "What's New" section of the instructions. Thus the update process could be incorporated into the CE production schedule without placing great demands on CE staff.

Comparison of the tax calculator results

To assess the accuracy of federal income tax estimated by the tax calculator, two analyses were conducted. First, interviewees' reported income tax liability was compared to the total federal taxes produced by the tax calculator. Second, BLS tax calculator estimates were compared to those of a tax calculator developed by the Congressional Budget Office (CBO). The results show that the BLS tax calculator accurately estimates federal income tax.

Internal comparison to federal income tax reported in the CE. This section analyzes the results of a matched-sample comparison between federal income tax reported by CUs and federal income tax estimated using the tax calculator. The sample was restricted to CUs that gave valid responses to the tax questions. Two variables are analyzed in this section: the difference in total tax and the difference in the average tax rate. As noted earlier, total federal income tax refers to the total amount of taxes the CU owes the IRS including subtractions for the EITC and the additional child tax credit. The tax calculator estimates the value of total taxes directly, whereas the CE survey estimates it using information on payroll tax deductions, additional taxes paid, and refunds received. Because the EITC and the additional child tax credit are distributed as refunds, it is not possible to distinguish them from overpayment of taxes in the CE.

Thus the two credits are included in both values of total tax. The difference in total tax is calculated as follows for each CU in the sample:

$$\text{Total tax difference} = \text{Tax calculator tax} - \text{CE tax} \quad (4)$$

The average tax rate is calculated as total tax divided by total income for each CU. Total tax is the same tax value used above, and total income is the sum of all taxable income sources, i.e., line 22 from the 1040 Individual Tax Return Form. The average tax rate is calculated in the same manner for both the tax calculator and the CE estimate:

$$\text{Average tax rate} = \text{Total tax paid} / \text{Total income} \quad (5)$$

For each CU, the difference is the average tax rate calculated by the tax calculator minus the tax rate estimated by the CE:

$$\text{Tax difference} = \text{Tax calculator average tax rate} - \text{CE average tax rate} \quad (6)$$

The data for this analysis are characterized as follows:

- The data are from the CE Quarterly Interview Survey for the third quarter of 2005, whose reference period includes April, May, and June; the third quarter was chosen because respondents are expected to have recently filed their taxes, increasing the accuracy of responses to questions on taxes and refunds.
- The tax calculator uses 2005 tax rates because most income reported refers to income earned in 2005.
- Imputed data are included.
- All CUs in the sample are in their second or fifth interview (the interviews when respondents are asked about income and taxes), contain only one TU, and report a positive value for both the CE total tax and the tax calculator total tax.

The results of this comparison are summarized in table 2, which compares income and federal income tax reported by respondents with those estimated using the tax calculator. The mean total tax for all filers reported in the CE survey is \$7,860.37, whereas the mean calculated by the tax calculator is \$2,446.89. The mean tax rate reported in the CE is 6 percent, and the value calculated by the tax calculator is 1.7 percent. The results of the matched-sample mean comparisons are varied but in general show that the tax calculator produces total taxes and average

Table 2. Mean total income, total federal income tax, and average tax rate for Consumer Expenditure Survey tax reporters and BLS tax calculator

Filing status	Tax reporters			Tax calculator			N
	Total income ¹	Federal income total tax ²	Average tax rate ³	Total income ¹	Federal income total tax ²	Average tax rate ³	
All filers	\$67,095.84 (80,598.31)	\$7,860.37 (24,603.43)	6.0 (.110)	\$67,320.87 (80,215.11)	\$2,446.89 (8,850.15)	1.7 (.268)	3,717
Single	54,683.16 (96,086.33)	7,002.17 (31,875.83)	7.9 (.075)	55,054.91 (95,808.56)	2,021.73 (6,117.77)	2.9 (.099)	1,744
Married, filing jointly	90,440.14 (61,757.97)	10,844.00 (16,343.49)	8.2 (.080)	90,416.15 (61,246.27)	3,477.09 (11,671.04)	2.6 (.099)	1,540
Head of household	34,064.65 (37,170.73)	705.41 (8,354.39)	-10.1 (.172)	34,584.39 (36,961.55)	495.35 (5,398.45)	-6.3 (.731)	433

¹ Total income refers to income for tax purposes only; it does not include workers' compensation or veterans' benefits, public assistance or welfare income, or the dollar value of food stamps.
² Federal income tax is the sum of the federal income tax values, including refunds, as described in equation (1).
³ Average tax rate is federal income tax divided by total income.

NOTE: Data are from the Consumer Expenditure third quarter 2005 quarterly interview and reflect consumer units that are in the second or fifth interview, contain only one tax unit, and have positive total tax from both the tax calculator and the CE. Numbers in parentheses are standard deviations.
 SOURCE: U.S. Bureau of Labor Statistics.

tax rates with differences that are large and statistically significant at the 5-percent level. (See table 3.) When the sample is partitioned by filing status, several of the cells no longer are statistically significant. For singles, the difference in the mean total tax is statistically significant, but the difference in the mean average tax rate is not. For CUs with a filing status of married, filing jointly, the differences in both mean total tax and mean average tax rate are significant. For head of households, neither is statistically significant. When these groups are further partitioned by income level, about half of the differences in total tax and tax rates are significant for each filing status, but the differences for CUs with income less than \$50,000 are not as large. The mixed results are likely due to the problems described above, including high nonresponse rates, unreliable reporting, and time-frame ambiguity. The large standard error associated with the differences in total tax and the average tax rate are likely due to small sample size (which is a result of restricting the sample to include only CUs with valid responses to the tax questions) and the large amount of variability in the input data.

Comparison to the CBO tax calculator. The CBO tax calculator, developed for its own internal use, produces tax tables identical to those published by the Statistics of Income Division of the IRS when it uses actual tax data from

the IRS. The CBO used its tax calculator to calculate taxes on the CE public use microdata. The comparison between the CBO tax calculator using the CE public use microdata and the BLS tax calculator using the CE microdata for internal use leads to the conclusion that the BLS tax calculator produces accurate estimates of total tax and average tax rates for CE consumer units.

The analyses of the difference in total tax and the difference in the average tax rate calculated by the BLS and CBO tax calculators follow the same methods as the internal comparison described in the previous section. The total tax difference and the average tax rate difference are calculated as follows:

$$\text{Total tax difference} = \text{Total tax from BLS tax calculator} - \text{Total tax from CBO tax calculator} \quad (7)$$

$$\text{Average tax rate difference} = \text{BLS average tax rate} - \text{CBO average tax rate} \quad (8)$$

The average tax rates are determined by dividing total tax by total income in the same manner depicted in equation (5).

The data for these analyses are characterized as follows:

- The data are from the CE Quarterly Interview Survey

second or fifth interview, contain only one tax unit, and have positive total tax from both the tax calculator and the CE. Numbers in parentheses are standard deviations.

SOURCE: U.S. Bureau of Labor Statistics.

for the third quarter of 2005.

- Both tax calculators use 2005 tax rates.
- Imputed data are included.
- All CUs in the sample are in their second or fifth interview, contain only one TU, and do not have top-coded data for any tax input values.¹²

Because the CBO tax calculator was not originally designed to be used with CE data, it does not account for some tax-related items included in the BLS tax calculator.

For this analysis, the following adjustments were made to the BLS tax calculator to mimic the CBO tax calculator:

- Dependents are limited to children or grandchildren of the reference person and are less than 19 years old or are less than 25 and in college.
- No dependents file separately, because the CBO tax calculator does not create multiple tax units.
- The credits calculated are limited to the child tax credit, the additional child tax credit, and the earned income tax credit.¹³

- Tax refunds are not considered taxable income.
- Deductions for contributions to retirement plans do not include payroll deductions.
- The self-employed do not pay an additional tax.

Tables 4 and 5 compare the results of the BLS and CBO tax calculators. The results are varied, but in general there are differences in the mean values of total income, total tax, and the average tax rates. Table 4 shows that the mean total taxes for the BLS and CBO tax calculators are \$4,091.16 and \$4,064.83, respectively. The mean average tax rate is 5 percent for both tax calculators. In table 5, which shows the mean difference in total federal income tax and average tax rate by filing status and income level, many of the cells are statistically different from zero at the 5-percent level of significance. The mean difference in total tax is \$26.33, and the mean difference in the average tax rate is 0.1 percentage points, both of which are statistically significant. The difference for singles in the total tax is \$20.89, which is not statistically significant, but the difference in the tax rate is 0.1, which is significant. The differences are significant for married, filing jointly CUs, with differences of \$34.18 in the total tax and 0.1 percentage points in the tax rate. The \$0.60 total tax mean difference for heads of households is not significant, but the tax rate difference of 0.1 percentage points is significant.

The statistically significant results are most likely due

to two major differences in the way the BLS and CBO tax calculators treat certain inputs to the tax calculators. First, the BLS calculator taxes all income sources at the same rate, whereas the CBO calculator treats dividends as capital gains, taxing them at 15 percent. Second, the CBO tax calculator converts quarterly medical expenditures to annual values, whereas the BLS calculator does not.¹⁴ When these differences are controlled for, the number of cells with a statistically significant value drops, especially for the mean total tax difference cells.

Tables 6 and 7 display results where the sample does not include CUs who report positive dividend income or do not have equal medical expenditures in both the BLS and CBO tax calculators.¹⁵ Table 6 reflects results similar to those in table 4, except that the means from the BLS and CBO tax calculators are greater than when no restrictions are applied, and the values calculated by the BLS calculator are closer to those calculated by the CBO. The mean total taxes for all filers are \$4,409.85 and \$4,400.58 for the BLS and CBO tax calculators, respectively. The mean tax rate is 6 percent for both calculators. Table 6 shows that the matched-sample comparison with CUs restricted to those without dividend income or medical expenditures results in a higher number of cells in which the difference is not statistically significant. In table 7, there are 16 cells in which the mean difference in total tax is significant and 14 for the mean average tax rate (out of a total of 30 cells),

Table 4. Mean total income, total federal income tax, and average tax rate from BLS and CBO tax calculators

i.e., about half of the cells display a difference that is statistically significant. Table 7 contains only 2 cells with a statistically significant difference for total tax and 12 for the average tax rate. Thus the results from the restricted sample illustrate that the two tax calculators compute total tax and average tax values that are nearly equal. Furthermore, the differences are not large enough to make a substantial difference, even when they are statistically significant.

THE RESULTS FROM THESE ANALYSES provide additional support for implementation of a tax calculator or

other method to improve the federal income tax data in the CE. The internal comparison reveals that the BLS tax calculator produces total tax and average tax rates that have large and statistically significant differences when compared with those estimated using CE interviewees' responses. The comparison to the CBO tax calculator illustrates that the BLS tax calculator accurately computes total tax and average tax rates. Because tax calculators and other methods of estimating or imputing tax data can be difficult and time consuming to create, many parties stand to benefit from the implementation of an official CE tax calculator. It will improve the quality of the

aftertax income data tables published by the CE, and it will widen the CE audience of researchers and other users to include those who are interested in studying after-tax income but do not have time, resources, or sufficient knowledge to create their own tax calculator. Although

the tax values produced by the BLS tax calculator are not perfect, this study demonstrates that a tax calculator such as the one discussed here greatly improves the quality of the tax data if tax inputs are properly defined and appropriate assumptions are made. □

Notes

ACKNOWLEDGEMENTS: The author would like to thank the anonymous reviewers who made helpful suggestions to the manuscript, as well as Steve Henderson, Laura Paszkiewicz, Geoffrey Paulin, and the team at CBO for their ongoing support throughout the project. Thanks to Carol Boyd Leon for editorial assistance. Many thanks are in order to Thesia Garner who taught me everything I know about the CE, and to her and Robert McClelland for making sure I never have to hire a tax accountant.

¹ For additional information on the Consumer Expenditure Survey, visit the CE webpage at www.bls.gov/cex/.

² The definitions of variables that follow are from the 2005 CE data dictionary.

³ Annual federal tax deducted from pay is calculated as the member's annual income from salary and wages multiplied by the percentage of the last pay check that went toward federal income tax. In other words, Annual federal tax = Annual salary and wages * (Amount deducted for federal tax from last pay / Amount of last pay check before any deductions).

⁴ Annual state and local taxes paid are calculated in the same manner as federal income tax (see endnote 3).

⁵ A consumer unit is a group of individuals who share expenses of housing, food, and other goods, and who live in the same residence. Of the sample in third quarter 2005, 54 percent of CUs contained members of the immediate family (i.e., husband and wife with or without children, or one parent with children), 27 percent were single individu-

als living by themselves, and 19 percent were “other,” i.e., other relatives or nonrelated people living in the residence.

⁶ These scenarios are true for respondents in their second and fifth interviews, when income and tax questions are asked. For respondents in their third and fourth interviews, the income and tax values are carried forward from the second interview. For those respondents, the time frame referenced will be even further in the past.

⁷ Although single people with dependents should file as single rather than as head of household if they contribute less than 50 percent toward household costs, the IRS suspects many singles incorrectly file as head of household. Thus the tax calculator assumes all single people with dependents file as head of household. The tax calculator considers married people who do not live with their spouses as unmarried, because the CE does not collect data on family members who do not live at the residence. A recent widow(er) is also considered unmarried because the CE cannot determine whether the person is a qualifying widow(er).

⁸ In the third quarter of 2005, two-thirds of the sample respondents who were eligible for the education deduction and credit owed less tax by taking the deduction. No dependents who filed separately had any tuition payments in that period.

⁹ Data are available on employer provided health insurance plans in the CE and could be incorporated into a future tax calculator.

¹⁰ Quoted from the 2006 Schedule R, Credit for the Elderly or the Disabled.

¹¹ From the CE data dictionary.

¹² The CE adds a top code to the public use microdata to remove

personally identifiable information in order to protect the privacy of CUs whose responses fall outside the normal range. These CUs are removed from this portion of the analysis because the top-coded inputs will produce inaccurate tax outputs.

¹³ The previous three adjustments imply that the tax calculators assume no one is disabled.

¹⁴ The CBO tax calculator multiplies the quarterly medical expenditures the CUs report by 4 to estimate annual medical expenditures. The BLS does not do this because the value of medical expenditures includes some large expenses which are not likely to occur each quarter, such as hospital visits. These large expenses significantly alter itemized deductions, and in some cases lead CUs to itemize when they would not otherwise do so. In some instances, this causes large changes in both total tax rates and average tax rates.

¹⁵ Before restricting the sample in these two ways (dividend income is zero and deductions for medical expenses are equal in both tax calculators), the tables were constructed with first one and then the other restriction. The tables in which dividend income is zero resulted in smaller total tax and average tax rate values since total income was reduced. The tables in which deductions for medical expenses are equal resulted in greater total tax and average tax rates because medical expenses are only equal for CUs that do not take any deduction. For many CUs this means they do not itemize their deductions, and thus their taxes are greater. When both restrictions are applied at once, total tax and the average tax rate are slightly greater than when no restrictions are applied because the effect of deleting CUs with medical deductions outweighs the effect of deleting CUs with dividend income.

Consumer Expenditure Survey Microdata Users' Workshop, July 2011

Geoffrey Paulin

The Consumer Expenditure Survey (CE) is the most detailed source of expenditures, demographics, and income collected by the federal government. CE data are collected by the U.S. Census Bureau in two component surveys: the Quarterly Interview Survey and the Diary Survey, which are described subsequently. (See Appendix A.) Every year, the CE program releases microdata from each of these surveys, which are used by researchers in a variety of areas, including academia, government, market research, and other private industry areas. In July 2006, the CE program office conducted the first in a series of annual workshops, to help users to better understand the structure of CE microdata; provide training in the uses of the surveys; and, through presentations by current users and interactive forums, promote conversation among the users, both to expand awareness within the community of common research interests and to discuss possibilities for collaboration. As part of these efforts, the past three workshops have also featured presentations by economists from the BLS regional offices who work with CE data. (See Appendix B.) The focus of this report is the most recent workshop, which was held in 2011.

Day one. William Hawk opened the first day of the 2011 workshop

Geoffrey Paulin is a senior economist in the Consumer Expenditure Surveys Program. Email: paulin.geoffrey@bls.gov.

with an overview of the CE in general, featuring topics such as how the data are collected and published. Bill Passero and Craig Kreisler then presented an introduction to the microdata, including an explanation of its features, such as “topcoding.”¹

The session that followed included a new feature for the workshop: presentations by first-time users of the CE microdata. The first presenter, Karen Ransom of the Southeast BLS Information Office in Atlanta, spoke about research into the effects of the recent “housing bubble” in various major metropolitan areas across the United States.² The second presenter, Kara Markley of the Mid-Atlantic BLS Information Office in Philadelphia, described her research into costs of commuting for residents of the Washington, DC, area, with particular emphasis on transit subsidies received by many of these commuters. Both presenters received their first training in use of the microdata within a few months of the workshop: Markley in March 2011 and Ransom in May 2011. The idea behind their presentations was to share their experiences with other novice users, including any tips or advice they had regarding working with the data.

The final speaker of the morning session, Tian Luo, of the Western BLS Information Office, a more experienced user of CE microdata,³ presented research on expenditures for higher education by the race of the reference person of the consumer unit.⁴ Like the others in this session, Luo is part of the Economic Analysis and Information (EA&I) staff at a BLS regional office. Since the 2009 workshop, at least one speaker from an EA&I staff has been included in the program. The inclusion of such a speaker is important to researchers,

because EA&I staff can provide information on data relevant to their local areas not only from the CE program, but from other programs sponsored by BLS (e.g., data on unemployment rates in Chicago). As resources and circumstances permit, future workshops will be planned to include both additional sessions aimed at highlighting experiences of first-time CE microdata users and continued presentations by EA&I staff of BLS regional offices.

Jonathan Fisher, of the Census Bureau, started the afternoon session with a presentation on how households adjust to changes in gasoline prices. The presentation was interesting for many reasons, including the fact that it used microdata from both the Diary and Interview Surveys. Jeff Lundy, Ph.D. candidate in sociology at the University of California at San Diego, then spoke about annual changes in wealth as measured by the Interview Survey.

The afternoon concluded with the first of two practical “hands-on” training sessions, with Laura Paszkiewicz and Craig Kreisler, expert users from the CE program staff, demonstrating how to use the files and variables to obtain estimates. During the session, participants practiced together on laptop computers.⁵

Day two. The second day opened with advanced topics, with Catherine Hackett of the BLS Division of Price Statistical Methods presenting technical details about sampling methods and construction of sample weights; Troy Olson of the CE program speaking on imputation and the allocation of microdata questions; and Bill Passero talking about common “calendar” versus “collection” period expendi-

tures.⁶ Following these presentations, Laura Paszkiewicz and Craig Kreisler held a practical training session and described specific steps required to compute calendar-year estimates, both unweighted and weighted.

After a break for lunch, the afternoon opened with an informational presentation followed by two research presentations. First, Jeff Lundy described his experiences in the BLS onsite researcher program, in which approved researchers can obtain access to confidential data provided by the Bureau.⁷ Next, Adam Bee, Ph.D, Notre Dame University and soon-to-be Census Bureau employee, described his research into the relationship between car ownership and employment. Finally, Megumi Omori, of Bloomsburg University, described her research into gift expenditures during the holiday season, a study that used data from the Diary Survey. These presentations were followed by Bill Passero's practical training session, which covered procedures for merging datasets and then manipulating the results to compute statistical measures.

The day concluded with special concurrent sessions. First, Terry Schau, managing editor, and Brian Baker, technical writer–editor, from the *Monthly Labor Review* described the publication process, from submission to printing, for authors interested in having their works appear in that journal. Concurrently, a panel from the Committee on National Statistics, established to make recommendations for a redesign of the CE data collection instrument, spoke on how the members consulted with expert users in order to understand how researchers use CE data and to solicit their ideas on how the data might be improved. Next, Steve Henderson delivered a brief “sneak peek” at changes to the microdata files that were sched-

uled to occur with the release of the 2010 microdata in September 2011. Finally, participants in an information-sharing group discussed each other's work with the data, their experiences at the workshop, and other topics in an unstructured setting.

Day three. The final day featured advanced topics, starting with Bill Passero's presentation of the use of data from survey respondents who completed all four published interviews. The issue was whether to combine the data collected or, instead, treat observations from each quarter independently. Coincidentally, Jonathan Fisher had developed his own weighting scheme for handling four-interview participants, and he described the methodology in the same session, marking the first time in the history of these workshops that circumstances combined to allow the sharing of a presentation between a BLS and a non-BLS researcher. In subsequent presentations, Neil Tseng explained how sales taxes are applied to expenditure reports during the data production process and Geoffrey Paulin described the proper use of imputed income data and the proper use of sample weights in computing population estimates. The latter session noted that the proper use of weights requires a special technique to account for sample design effects that, if not employed, result in estimates of variances and regression parameters that are incorrect.⁸ The session concluded with a presentation by Laura Paszkiewicz describing “paradata” regarding the interview process itself, such as the interviewee's contact history and the type of interview obtained—via personal visit or by telephone. The workshop was the second one to include this feature, as paradata were not added to the public-use microdata files un-

til the release of the 2009 microdata a few months after the 2010 workshop. The morning concluded with the final practical training session of the workshop, featuring a discussion of a program included with the microdata for use in computing proper standard errors for means and regression results when using unweighted nonincome data; population-weighted nonincome data; and multiply imputed income data, both unweighted and population weighted.

The afternoon session included two research presentations. First, Brian Melzer, of Northwestern University, investigated the effects of mortgage debt overhang on housing investment and demonstrated that, although homeowners with negative equity cut back substantially on mortgage principal payments, home improvements, and home maintenance spending, these households showed no difference in durable spending on automobiles, furniture, and home appliances—investments that are not attached to the home. In the second presentation, Sayeh Nickpay, of the University of Michigan, described work investigating the seasonality of medical expenditures and flexible spending accounts. Next, Anthony Damico, of the Kaiser Family Foundations, demonstrated a programming code used in the computation of health care expenditures by Medicare households. The 2011 workshop concluded with CE program staff soliciting feedback from the participants.

2012 workshop

The next microdata users' workshop will be held July 18–20, 2012, and will be free of charge to all participants, although advance registration is required. For more information about this and previous workshops, visit the CE website (www.bls.gov/cex) and

look for “Annual Workshop” under the left navigation bar entitled “PUBLIC USE MICRODATA.”

Abstracts of presentations

Following are abstracts of the papers described at the conference, listed in the order in which they were presented and based on summaries written by their authors:

Jonathan Fisher, U.S. Census Bureau, “Household Adjustments to Gasoline Price Changes” (Interview and Diary Surveys), day one.

This paper uses aggregate U.S. data, along with household data from the Consumer Expenditure Survey, to explore the adjustments households make to changes in gasoline prices. The paper begins by using aggregate data to show long-run trends in gasoline prices and various measures of gasoline demand. Although gasoline prices have been volatile, the share of total expenditures spent on gasoline has been relatively insensitive to prices, but the level of gasoline expenditures has moved in tandem with gasoline prices.

To investigate how households respond to changes in gasoline prices, the paper then moves to an analysis of household data from the Consumer Expenditure Diary and Interview Surveys. The analysis confirms the well-known finding that the demand for gasoline is inelastic and relatively stable over time and, using the Almost Ideal Demand System of Angus Deaton and John Muellbauer,¹⁰ documents how households alter their nongasoline consumption due to changes in gasoline prices. The paper’s chief finding is that households decrease expenditures primarily on motor vehicles and services.

Jeff Lundy, Ph.D. candidate, Univer-

sity of California at San Diego, “Measuring Annual Change in Household Wealth with the CE Survey” (Interview Survey), day one.

The Consumer Expenditure Survey tracks the value of assets and liabilities of a large rotating sample of U.S. households. Unfortunately, researchers studying household wealth have largely neglected this potential resource, relying instead on aggregate statistics. Although aggregate wealth statistics are suggestive of individual household decisions, the Consumer Expenditure Survey has the potential to offer a more direct picture of how U.S. households manage their finances.

To validate the survey’s potential for measuring changes in household wealth, this paper compares the Consumer Expenditure Survey with the well-established Flow of Funds Accounts. Results indicate that the Consumer Expenditure Survey measures change in wealth well at the household level.

In addition, the paper examines the extent of gains and losses in wealth for the 2004–2009 period. Among the findings of the research are that the number of households with annual wealth losses is considerably higher than the number of households with lifetime wealth losses and that wealth gains vary substantially across households in various asset ownership groups. These demonstrative findings reveal the potential of the Consumer Expenditure Survey in examining how households’ financial and demographic characteristics affect their annual change in net wealth.

Adam Bee, Ph.D., University of Notre Dame, “The Effect of Car Ownership on Employment: Evidence from State Insurance Rate Regulation” (Interview Survey), day two.

Various economic theories suggest

that one reason for low rates of employment among low-skilled, inner-city residents is that they are spatially separated from jobs that have moved out to the suburbs. To test that hypothesis, this paper exploits the variation in state regulation of prior approval of insurance rates. More regulation has been shown to suppress auto insurance prices, thereby decreasing the cost of owning a car. The analysis finds that rate regulation increases the proportion of multicar households, among married couples with children. In those households, the additional car encourages mothers to decrease their labor supply while their husbands increase theirs. One possible explanation of this finding is that second cars are stronger complements to time spent in home production (especially child rearing) than they are to time spent in the labor market.

Megumi Omori, assistant professor of sociology, Department of Sociology, Social Work, and Criminal Justice, Bloomsburg University, “What to Buy, When to Buy, and How Much to Spend: Gift Purchasing Between Black Friday and Christmas Eve in 2009” (Diary Survey), day two.

Gift giving has been identified as serving important functions in our society. For example, it shows one’s identity, taste, and status. Gift giving is also a sign of love, and it maintains relationships among family members. Furthermore, it creates boundaries between and within social groups. Gift-giving rituals are common during the holiday season, and it seems that almost everyone is involved in gift shopping. Although several studies have examined gift-giving behavior, such as what to give, who does the shopping, and how much to spend, most of them employed rather small, regionally limited samples.

To my knowledge, there is only one study that used nationally representative data to examine expenditures on gifts: using the 1984–1985 Consumer Expenditure Interview Survey, Thesia Garner and Janet Wagner found that 90 percent of their sample reported some gift expenditures.¹¹ Among those who spent money on gifts, sample households allocated 3.7 percent of their total expenditures on gifts for other than household members. The authors also found that family size, total expenditures, and education of the reference person correlate positively with gift expenditures.

This paper proposes to update Garner and Wagner’s study by using the most recent 2009 Consumer Expenditure Survey (CE). Differing from their study, it utilizes the CE Diary Survey Expenditure Files and has five objectives:

1. To estimate the proportion of U.S. households that purchase gifts for other than their own household members (hereafter, simply, gifts) and compare that proportion with figures used in other studies (Variable: GIFT).
2. To estimate expenditures on gifts and the proportion of gift expenditures to total expenditures (Variable: COST).
3. To identify the day and date of gift purchasing between Black Friday and Christmas (Variable: QREDATE).
4. To identify items purchased as gifts during the same period (Variable: UCC)
5. To compare the cost of items purchased as a gift and for household members (Variable: COST) and for other than household members, by household characteristics (FMLD files).

Brian Melzer, assistant professor, Department of Finance, Northwestern University, “Effects of Mortgage Debt Overhang on Housing Investment” (Interview Survey), day three.

Homeowners with negative equity have less incentive to invest in their property. They face a debt overhang: some value created by equity investments in the property is expected to go to the lender. Using rich microdata on household expenditures, this paper shows that debt overhang plays an important role in household financial decisions. Specifically, it finds that homeowners with negative equity cut back substantially on mortgage principal payments, home improvements, and home maintenance spending. At the same time, these households show no difference in durable spending on automobiles, furniture, and home appliances—investments that are not attached to the home. The decline in mortgage principal payments is particularly large for negative-equity homeowners in nonrecourse states, where strategic default is more likely because lenders have a claim, albeit limited, on nonhousing wealth. Debt overhang, rather than financial constraints, best explains this set of facts. Given the prevalence of negative home equity in today’s housing market, the findings suggest that home values will grow more slowly in the future because of underinvestment. In addition, the potential deadweight loss due to home foreclosures is only part of the economic inefficiency that follows the spree of mortgage borrowing in the 2000s and the subsequent real estate price decline.

Sayeh Nikpay, Ph.D. candidate, University of Michigan, “Seasonality of Medical Expenditures and Flexible Spending Accounts” (Interview Survey), day three.

This paper uses microdata from the

1999–2009 Consumer Expenditure Surveys to examine the seasonality of purchases of medical goods that are eligible for reimbursement from a flexible spending account (FSA). Because FSA contributions are made annually and cannot be carried over from year to year, households that overcontribute to an FSA should spend disproportionately on FSA-eligible goods at the end of the year in order to avoid forfeiting their contribution. In the paper, the author constructs a monthly panel dataset of consumer units’ expenditures on FSA-eligible items, such as eyeglasses, durable medical equipment, and clinician fees, and non-FSA-eligible items, such as men’s and women’s apparel. Then, with the use of the Health Tracking Household Survey to impute the likelihood of having an FSA on the basis of consumer unit characteristics, the paper compares monthly expenditures for FSA and non-FSA eligible goods over the year.

Anthony Damico, The Kaiser Family Foundation, “Health Care Spending by Medicare Recipients: How to Analyze CE Data by Expenditure Category for Any Population Group of Interest” (Interview Survey), day three.

This presentation is designed to teach users how to define any population of interest from among the CE Interview files and then, in three steps, rapidly produce line, bar, or pie charts about any expenditure category of interest. First, the presentation walks through how to narrow expenditure categories to only the ones of interest. The presentation gives an example using health care, to which anyone can make a few nominal changes to analyze his or her category of interest. Second, by making some minor edits to the SAS program included with the dataset (see SAS

program folder, “Intrvw Mean and SE.sas”), one can limit the output to only the expenditures of interest, with the output broken out by any demographic group that one can identify by means of the family files. Third, in order to increase the number of ways to identify demographic groups, the presentation reviews how to merge

the family files with some of the other interview files. After completing these three steps, the researcher will have an output file containing the expenditure categories that he or she is most interested in, broken down and filtered according to precise analytic needs. Here, the example used is again household health care ex-

penditure categories, but now among Medicare beneficiaries, broken down by all sorts of different demographic groupings. To add one more analytic “trick,” the presentation briefly reviews a technique that can be used to quickly create an “all other” expenditure category, a category containing multiple categories. □

BLS speakers

Staff of the CE program

William Hawk, Economist, Branch of Information and Analysis (BIA); day one
 Craig Kreisler, Economist, BIA; days one and two
 Steve Henderson, Supervisory Economist, Chief, BIA; days one (welcoming remarks) and two
 Troy Olson, Supervisory Economist, Chief, Phase 3 Section, Branch of Production and Control (P&C); day two
 Bill Passero, Senior Economist, BIA; all days
 Laura Paszkiewicz, Senior Economist, BIA; all days
 Geoffrey Paulin, Senior Economist, BIA; day three
 Neil Tseng, Senior Economist, P&C; day three

Other BLS speakers

Brian Baker, Technical Writer–Editor, Office of Publications and Special Studies (OPUBSS), *Monthly Labor Review* Branch; day two
 Catherine Hackett, Mathematical Statistician, Division of Price Statistical Methods; day two
 Tian Luo, Economist, Office of Field Operations, Western Information Office in San Francisco, Division of Economic Analysis and Information; day one
 Kara Markley, Supervisory Economist, Office of Field Operations, Mid-Atlantic BLS Information Office in Philadelphia, Division of Economic Analysis and Information; day one
 Karen Ransom, Supervisory Economist, Office of Field Operations, Southeast BLS Information Office in Atlanta, Division of Economic Analysis and Information; day one
 Terry Schau, Managing Editor, OPUBSS, *Monthly Labor Review* Branch; day two

Speakers from outside BLS:

Adam Bee, Ph.D., University of Notre Dame, “The Effect of Car Ownership on Employment: Evidence from State Insurance Rate Regulation” (Interview Survey), day two
 Anthony Damico, The Kaiser Family Foundation, “Health Care Spending by Medicare Recipients: How to Analyze CE Data by Expenditure Category for Any Population Group of Interest” (Interview Survey), day three
 Jonathan Fisher, U.S. Census Bureau, “Household Adjustments to Gasoline Price Changes” (Interview and Diary Surveys), day one; presentation on computation and use of longitudinal weights (Interview Survey), day three
 Jeff Lundy, Ph.D. candidate, University of California, San Diego, “Measuring Annual Change in Household Wealth with the CE Survey” (Interview Survey), day one
 Brian Melzer, assistant professor, Department of Finance, Northwestern University, “Effects of Mortgage Debt Overhang on Housing Investment” (Interview Survey), day three. Working paper available online at http://www.kellogg.northwestern.edu/faculty/directory/melzer_brian.aspx#research.
 Sayeh Nikpay, Ph.D. candidate, University of Michigan, “Seasonality of Medical Expenditures and Flexible Spending Accounts” (Interview Survey), day three
 Megumi Omori, assistant professor of sociology, Department of Sociology, Social Work, and Criminal Justice, Bloomsburg University, “What to buy, When to Buy, and How Much to Spend: Gift Purchasing Between Black Friday and Christmas Eve in 2009” (Diary Survey), day two

NOTES

¹ To preserve the confidentiality of the data, values for some variables, such as income sources and certain expenditures (rent, among others) are topcoded. In this process, values that exceed a predetermined critical value are replaced with a new value. In each case, changed values are flagged for user identification. Details about topcoding are provided in the public-use microdata documentation for the year of interest. (See, for example, *2010 Consumer Expenditure Interview Survey*, Public Use Microdata, User’s Documentation, September 27, 2011, <http://www.bls.gov/>

[cex/2010/csxintvw.pdf](http://www.bls.gov/cex/2010/csxintvw.pdf).)

² Coresearchers of the work are Jacqueline Midkiff, of the Mountain–Plains BLS Information Office in Kansas City, and Cheryl Abbot, of the Southwest BLS Information Office in Dallas, both of whom attended the workshop.

³ Luo used CE data in his research into educational expenditures for a project conducted while he was an undergraduate at the University of California at Berkeley.

⁴ See appendix A for the definition of *reference person* and *consumer unit*.

⁵ Topics covered included a brief overview of the microdata files and structure, summary variables (i.e., aggregated values for various expenditure categories), and estimating unweighted and weighted mean expenditures by using FMLY, MEMB, and MTAB files from the Interview Survey and FMLY and EXPN files from the Diary Survey. For each survey, the FMLY file contains information about the consumer unit as a whole, such as its region of residence, and summary variables for expenditure categories, such as total expenditures, housing,

and apparel in the Interview Survey and fresh fruits, fresh vegetables, nonalcoholic beverages, and nonprescription drugs and supplies in the Diary Survey. The MEMB files in the Interview Survey contain information about each member of the consumer unit, such as the member's age, ethnicity, and educational attainment. However, the files contain no information on expenditures, because such information pertains to the consumer unit as a whole and therefore is not available on specific members, except in single-member consumer units. The MTAB files in the Interview Survey include information on expenditures at highly detailed levels (e.g., food or board at school, rent of dwelling, bedroom linens, girls' hosiery, and boys' footwear). The EXPN files in the Diary Survey are similar to the MTAB files in the Interview Survey, in that they also include information on expenditures at detailed levels (e.g., apples, bananas, oranges, other fresh fruits, and citrus fruits excluding oranges, which together aggregate to form the summary variable "FRSHFRUT"

in the Diary Survey FMYL file). There are also EXPN files in the Interview Survey, which contain even more detailed breakdowns for certain expenditures, and other detailed information on some items, such as the number of members in the consumer unit who are covered by a particular health insurance policy. Some of the differences among all these files were discussed during the overview of the file structure delivered on the first day of training.

⁶ In the Interview Survey, the 3-month recall period may include expenditures made in the previous year. For example, persons interviewed in February will report expenditures occurring in November and December of the previous year, as well as expenditures occurring in January of the current year. Those interested in computing expenditures for the collection period can sum expenditures for these 3 months to obtain their results. However, those interested in computing expenditures that occurred within the same calendar year must take extra steps to include the November and December expenditures only

with the previous year's expenditures and the January expenditures only with the current year's expenditures.

⁷ See "Researcher Access to Confidential Data Files at the BLS" (U.S. Bureau of Labor Statistics, Aug. 22, 2011), <http://www.bls.gov/bls/blsresda.htm>.

⁸ The CE sample design is pseudorandom. However, the proper use of weights requires the use of the method of balanced repeated replication.

⁹ For direct access to this information, see "Consumer Expenditure Survey (CE) Microdata Users' Workshop and Survey Methods Symposium, July 17–20, 2012" (U.S. Bureau of Labor Statistics, Mar. 9, 2012), <http://www.bls.gov/cex/csxannualworkshop.htm>.

APPENDIX A: About the CE data

Consumer unit. The basic unit of analysis in the CE is the consumer unit. In general, a consumer unit consists of any of the following: (1) all members of a particular household who are related by blood, marriage, adoption, or some other legal arrangement; (2) a person living alone or sharing a household with others or living as a roomer in a private home or lodging house or in permanent living quarters in a hotel or motel, but who is financially independent; (3) two or more persons living together who use their incomes to make joint expenditure decisions. Financial independence is determined by spending behavior with regard to the three major expense categories: housing, food, and other living expenses. To be considered financially independent, the respondent must provide at least two of the three major expenditure categories, either entirely or in part.

Collection and methodology. Since 1980, the Quarterly Interview and Diary Surveys have been collected on an ongoing basis. The Quarterly Interview Survey is designed to collect expenditures for big-ticket items (e.g., major appliances; cars and trucks) and recurring items (e.g., payments for rent, mort-

gage, or insurance). Some expenditures, such as food at home, are collected globally.¹ In addition to information on expenditures, demographics, and income, information about assets and liabilities is collected. In this Interview Survey, participants are visited once every 3 months for five consecutive quarters. Data from the first interview are collected only for bounding purposes and are not published.² Since April 2006, about 7,000 consumer units have participated in the Interview Survey each quarter.

In the Diary Survey, participants record expenditures daily for 2 consecutive weeks. The survey is designed to collect expenditures for small-ticket and frequently purchased items, such as detailed types of food (white bread, ground beef, butter, lettuce). Since April 2006, about 7,000 consumer units participate annually. Because they complete a separate diary each week, approximately 14,000 diaries are collected each year.

Reference person. The reference person for the consumer unit is the first person mentioned when the respondent is asked to name the person or persons who own or rent the home.

Notes to Appendix A

¹ That is, the respondent is asked to provide an estimate of total expenditure for these items, rather than collecting detailed information on items composing the category.

² A bounding interview collects information aimed at alerting the interviewer to probe in cases where the purchase of a big-ticket or infrequently purchased item reported in one interview is reported, perhaps inadvertently, in the next interview. For example, if the re-

spondent reports purchasing a refrigerator in the first interview and also reports such a purchase in the second interview, the interviewer can ask followup questions to ascertain whether the refrigerator reported in the second interview was the refrigerator reported in the first interview. The same process is followed in the second through fifth interviews when similar cases occur. That is, the second interview provides bounding information for the third interview, and so forth.

APPENDIX B: History of the workshops, 2006–2010

In July 2006, the CE program conducted the first in a series of annual workshops. Held each year in the conference facilities of the Bureau of Labor Statistics (BLS) headquarters in Washington, DC, the workshop has included speakers demonstrating features of the data, as well as reports from researchers who have used these data in their work. Over time, the format has changed to incorporate suggestions from participants, but the basic elements have remained intact.

The first three workshops, held in 2006–2008, took place over 2 days and included concurrent training sessions for novice users and intermediate or expert users. In July 2009, the program was expanded from 2 days to 3 days. The first day was designed especially for new users, including those who had never used the data. The second day was designed to feature research from users outside the BLS. The third day was designed especially for more experienced users. The program was arranged in this way to accommodate as many participants as possible. That is, any attendee could participate in 1, 2, or all 3 days of the workshop and

benefit from sessions geared toward his or her level of expertise.

Starting with the next workshop, in July 2010, the format was changed slightly. On the basis of comments from the 2009 workshop, research presentations were spread out over the 3 days. Nevertheless, the training and data-descriptive sessions continued to be organized progressively, so that attendees could still plan to attend a combination of days appropriate to their levels of expertise in using the data. In addition, researchers did an excellent job presenting not just results of their work, but processes used, problems or data limitations encountered, how they were handled, and other practical considerations.

Finally, a new feature called “Meet with an Expert” was initiated in the 2010 workshop. In this feature, participants had the opportunity to make one-on-one appointments with an expert data user from the staff of the Consumer Expenditure Survey program for an in-depth discussion about their specific or general questions regarding the use of the data. Several participants did so then and in the 2011 workshop.

Do little engines really do big things?

In “Are Small Businesses the Biggest Producers of Jobs?” (*The Regional Economist*, Federal Reserve Bank of Saint Louis, April 2011, <http://www.stlouisfed.org/publications/re/articles/?id=2087>), Kevin L. Kliesen and Julia S. Maués examine the data behind a claim that is routinely asserted by politicians of every persuasion, namely, that “small businesses” (however they may be defined) are the job creation engines of the U.S. economy, responsible for generating a disproportionately large share of new jobs relative to larger firms.

The article traces the claim to its root. In 1979, David Birch, who was then a professor at the Massachusetts Institute of Technology, wrote that firms with 20 or fewer employees accounted for two-thirds of new jobs created during the early 1970s, and firms with 100 or fewer employees accounted for 82 percent of new jobs. Correspondingly, large firms (those with 500 or more employees) accounted for only a small share (15 percent) of new jobs. Birch’s findings were subsequently refined by him and revised by others, but the idea that small businesses account for most of the country’s job growth was soon ingrained as fact in the nation’s political discourse.

It is well known that the failure rate of small businesses is notably high. It takes time for businesses that do not survive to be born and live, then to fail and die. During that time, the business increases the number of jobs, but only in the short run. Later, as it fails, the business decreases the number of jobs. Think of the large number of small

businesses that come into existence each year, some of them destined to fail and be forgotten, others able to turn a profit and continue in operation—with a few in the latter group eventually outgrowing the “small business” category—and it’s easy to see why, as a whole, small businesses account for such a large portion of new jobs.

However, looking at job creation statistics tells only half the story. True, small businesses, as they come into being and begin to grow, account for an attention-getting share of job creation. It is also true that as some of them struggle and fail, they also account for a large share of job destruction. The authors note that “a common confusion between net and gross job creation” occurs when the focus is placed only on the number of jobs created by small businesses and no attention is paid to the number of jobs destroyed as some small businesses become smaller or cease operations entirely. The notable hundreds of thousands of new jobs are transformed into dozens of thousands when job losses are subtracted from gross job gains to yield net job gains. When the focus of research is shifted to net job gains, it can be seen that large firms create the most jobs. One illustration of this in the article is a table of data from the BLS Business Employment Dynamics program (www.bls.gov/bed/) showing that firms with 500 or more employees had the largest number of net job gains over the 1992–2010 period.

Why Greek sovereign debt matters to us

Because the financial crisis in Greece could lead to political and

civil unrest within the country and has caused concerns about the stability of the euro and its impact on the world economy, Greek financial troubles are of international importance.

In “Demystifying Sovereign Debt in Greece: Why It Matters to Us” (*EconSouth*, Federal Reserve Bank of Atlanta, second quarter 2010, http://www.frbatlanta.org/documents/pubs/econsouth/10q2_greece.pdf), economic analyst Andrew Flowers explains the Greek money crisis, its potential repercussions on both the euro nations and the global economy, and what lessons it holds for other countries dealing with large budget deficits.

Flowers notes that while Greece has led the pack among euro countries in terms of running large budget deficits and carrying a high debt-to-GDP (gross domestic product) ratio, Greece is not alone in its fiscal problems. Several other European countries, including Italy, Ireland, Spain, and Portugal, are also dealing with large deficits.

The severity of Greece’s fiscal crisis was revealed in October 2009 by the newly appointed Greek finance minister. Investors began to lose confidence in the country’s sovereign debt, resulting in widening bond and credit default swap spreads. By December of the same year, the government proposed the first of several austerity measures to help lower the budget deficit; these measures were met with investor skepticism and objections from protestors. “The political and financial drama in Greece has since oscillated between greater protests and renewed, bolder austerity plans,” explains Flowers.

Flowers notes that some analysts worry that the Greek crisis could

also affect other European countries, especially if a large European financial institution were to fail. In addition, the effects of the crisis could spread outside of Europe. Flowers points to troubling signs of strain in the interbank lending market, which could feed through to businesses and consumers around the world.

Concerns over potential spillover

effects to other fiscally troubled countries in the euro area prompted a pan-European response to the crisis. In May 2010, the European Commission unveiled a rescue package totaling \$957 billion for troubled European governments. However, euro-area countries must still enact tough budget and labor reforms to successfully stabilize their economies, says Flowers.

There are several lessons to be learned by governments all over the world battling large financial deficits. Yet, as Flowers concludes, “time will tell how Greece and its European partners will regain stability and the confidence of investors. For other countries, the Greek fiscal crisis has been a sobering reminder of how precarious government finances are in this postrecession world.” □

The real story of the Middle West

Remaking the Heartland: Middle America since the 1950s. By Robert Wuthnow, Princeton, NJ, Princeton University Press, 2011, 358 pp., \$35/hardback

Sociologist Robert Wuthnow used to subscribe to the view of the American Middle West (referred to as Middle America in the book's title) as a region in long-term decline, and he decided to write a book explaining the decline as evidenced by ghost towns, reports of joblessness, and other signs of decreasing vitality. But after doing a great deal of research, he realized that the true story of the Middle West, or heartland, from the 1950s to the present was considerably different from the conventional story that he had accepted. With an overall approach that "treads the line between history and social science," Wuthnow argues that, rather than declining, the Middle West has been remade in a way consistent both with its traditional values and with modern changes in society and technology. Pain tends to accompany any large transformation, and the transformation of the heartland is no exception to that tendency: the region certainly has experienced its share of economic pain. And it is sometimes stereotyped as culturally backward. But Wuthnow asserts that, on the whole, the region is both economically and culturally vibrant.

In *Remaking the Heartland*, the Middle West is defined as the traditional U.S. Census Bureau West North Central Division states of Iowa, Kansas, Nebraska, Minnesota,

Missouri, North Dakota, and South Dakota, together with Arkansas and Oklahoma. To research this region, Wuthnow chose to use multiple methods. He analyzed statistical data from sources such as the Census Bureau and the Bureau of Labor Statistics; studied media reports, books, and other documents; and, with the help of research assistants, conducted in-depth interviews with people who live in or grew up in the heartland. Wuthnow's use of mixed methods is easily justified: it is hard to imagine one method being sufficient to tell the full story of the transformation of an entire region of the country.

The Middle West used to be a region known for small towns, a strong dependence on agriculture, and little ethnic diversity. Small towns are still a very important part of the Middle West, but there are now a greater number of large cities and suburbs, a more advanced agriculture industry, many new industries, more overall economic prosperity, and increased ethnic diversity. What brought about the transformation of the Middle West? Wuthnow contends that the change was not imposed from the outside but instead came from within the heartland—certainly a believable contention given that history has shown that positive changes are far less likely to last when they are imposed from outside. Still, part of the story of the Middle West's transformation is its increasing economic links with other parts of the United States and other countries as well. But in Wuthnow's opinion, the primary source of the heartland's metamorphosis is the strength of the social institutions that were in place even before the 1950s. These institutions

include "the market towns, the farmsteads, the one-room schools, the townships, the rural cooperatives, and the manufacturing centers that gave the region its identity."

Another source of strength in the Middle West is the ability of its people to adapt when faced with adverse circumstances. To understand the Middle West of the 1950s, it is of course necessary to look back further in time, and one of the best examples of adverse circumstances with long-lasting effects is the Great Depression and the Dust Bowl. Throughout the 1940s and even into the 1950s, times continued to be tough. There is a romantic view of the 1950s heartland as "prospering from good crops, with happy housewives preparing luscious meals on modern kitchen appliances," but Wuthnow notes that most families did not live in that way at the time. Many homes still did not have electricity or telephone service, for example. Crop yields tended to fluctuate dramatically. Both in the past and today, one of the ways that people have adapted to adverse circumstances is by moving. Another misconception that Wuthnow points out is the idea of the Middle West as a place where most families have put down roots in a particular town or county and remained for generations. In fact, the heartland has always been a place where people tend to be quite mobile. Today, there are large flows of people moving both into and out of the Middle West; for example, in 2006, about 40 percent of the residents of Kansas were originally from another state. One of the main reasons that the Middle West has been seen as a region in decline is the fact that numerous small towns have been shrinking in population.

Despite these declines in population, Wuthnow points out that many people who leave small communities in the Middle West simply move to larger towns that also are in the Middle West.

Remaking the Heartland tells a number of interesting stories about Middle Western literature, films, television shows, and other entertainment. For example, Wuthnow discusses *Little House on the Prairie*, *The Wizard of Oz*, and Buffalo Bill's *Wild West* shows. Wuthnow notes that the location of the Wild West in people's imaginations started shifting westward in the 1800s. During the lifetime of Buffalo Bill (1846–1917), the Wild West came to be associated far more with the Southwest of the United States than with the Middle West.

One of the chapters of the book is dedicated to a discussion of education in the Middle West. Ever since the 1800s, most of the heartland states have had particularly strong schools. Most of the early migrants to the Middle West were from states with high levels of education, such as New York, Pennsylvania, and Ohio. Moreover, those who migrated were more educated, on average, than those who remained behind. Today, Middle Western communities still tend to place a high priority on public education. However, they struggle with brain drain, especially among people who graduate from college in the Middle West and then move elsewhere. In addition, given a history of oppression by Whites, it is not surprising that Blacks in the heartland have historically been much less educated than Whites.

The Middle West obviously is well known for agriculture, but another key part of its economy—one that has grown immensely over the past few decades—is agribusiness. Companies like Tyson, ConAgra, and Iowa Beef Processors provide many thousands of jobs. Many of these jobs go to immigrants, which has increased ethnic diversity. However, given that meat processing is an industry with notoriously dangerous working conditions, the impact of agribusiness has not been completely positive. The rapid growth of “edge cities” is another topic that the book discusses at length. Many people from these large suburban cities commute to the central city to work, but a large number of government agencies and private companies have chosen edge cities for their offices. It was not obvious that edge cities would develop as much as they have, because it was hard to imagine enough jobs in the central cities to support populous suburbs. But companies such as Garmin in Kansas and General Mills and Medtronic in Minnesota have provided jobs.

The book ends with an afterword. Wuthnow himself is from the Middle West, and here, for the first time, he discusses several of his own connections to the region. Wuthnow performs admirably in his mission to write from an objective standpoint throughout the main chapters. After more than 200 pages of objectivity, it is actually a bit of a treat to read something more personal.

Although Wuthnow does not state it explicitly, an underlying part of his central argument is that, taken altogether, the people of the Middle

West are not much different from people elsewhere. They adapt to adverse circumstances, they change with the times, and their social institutions help to push them forward. This implicit point, though not surprising, is an important one given the many negative stereotypes of the heartland that tend to persist. In addition, the book does a good job of mixing statistical analysis with interesting stories of individuals, towns, and institutions.

Despite the many strengths of *Remaking the Heartland*, the book could have been improved by telling the story of another region (in the United States or elsewhere) to serve as a point of comparison with the story of the Middle West. It is a bit difficult to fully accept the argument of social institutions and adaptability remaking the heartland without an analysis of the history of at least one other region and how the same variables in that other region affected its outcome. Even just one chapter discussing one other region could corroborate the thesis of the book (or perhaps weaken it!). Notwithstanding this weakness, it is clear that a great deal of time and care went into the research for the book. Although I take its conclusions with a small grain of salt, I do believe *Remaking the Heartland* to be a trove of interesting and important information about a region of the United States that too often is ignored. □

Notes on Current Labor Statistics

This section of the *Review* presents the principal statistical series collected and calculated by the Bureau of Labor Statistics: series on labor force; employment; unemployment; labor compensation; consumer, producer, and international prices; productivity; international comparisons; and injury and illness statistics. In the notes that follow, the data in each group of tables are briefly described; key definitions are given; notes on the data are set forth; and sources of additional information are cited.

General notes

The following notes apply to several tables in this section:

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect on the data of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might prevent short-term evaluation of the statistical series. Tables containing data that have been adjusted are identified as “seasonally adjusted.” (All other data are not seasonally adjusted.) Seasonal effects are estimated on the basis of current and past experiences. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years.

Seasonally adjusted data appear in tables 1–14, 17–21, 48, and 52. Seasonally adjusted labor force data in tables 1 and 4–9 and seasonally adjusted establishment survey data shown in tables 1, 12–14, and 17 usually are revised in the March issue of the *Review*. A brief explanation of the seasonal adjustment methodology appears in “Notes on the data.”

Revisions in the productivity data in table 54 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month-to-month and quarter-to-quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average All-Items CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data—such as the “real” earnings shown in table 14—are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current-dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100. For example, given a current hourly wage rate of \$3 and a current price index number of 150, where 1982 = 100, the hourly rate expressed in 1982 dollars is \$2 ($\$3/150 \times 100 = \2). The \$2 (or any other resulting

values) are described as “real,” “constant,” or “1982” dollars.

Sources of information

Data that supplement the tables in this section are published by the Bureau in a variety of sources. Definitions of each series and notes on the data are contained in later sections of these Notes describing each set of data. For detailed descriptions of each data series, see *BLS Handbook of Methods*, Bulletin 2490. Users also may wish to consult *Major Programs of the Bureau of Labor Statistics*, Report 919. News releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule appearing on the back cover of this issue.

More information about labor force, employment, and unemployment data and the household and establishment surveys underlying the data are available in the Bureau’s monthly publication, *Employment and Earnings*. Historical unadjusted and seasonally adjusted data from the household survey are available on the Internet:

www.bls.gov/cps/

Historically comparable unadjusted and seasonally adjusted data from the establishment survey also are available on the Internet:

www.bls.gov/ces/

Additional information on labor force data for areas below the national level are provided in the BLS annual report, *Geographic Profile of Employment and Unemployment*.

For a comprehensive discussion of the Employment Cost Index, see *Employment Cost Indexes and Levels, 1975–95*, BLS Bulletin 2466. The most recent data from the Employee Benefits Survey appear in the following Bureau of Labor Statistics bulletins: *Employee Benefits in Medium and Large Firms*; *Employee Benefits in Small Private Establishments*; and *Employee Benefits in State and Local Governments*.

More detailed data on consumer and producer prices are published in the monthly periodicals, *The CPI Detailed Report* and *Producer Price Indexes*. For an overview of the 1998 revision of the CPI, see the December 1996 issue of the *Monthly Labor Review*. Additional data on international prices appear in monthly news releases.

Listings of industries for which productivity indexes are available may be found on the Internet:

www.bls.gov/lpc/

For additional information on international comparisons data, see *International Comparisons of Unemployment*, Bulletin

1979.

Detailed data on the occupational injury and illness series are published in *Occupational Injuries and Illnesses in the United States, by Industry*, a BLS annual bulletin.

Finally, the *Monthly Labor Review* carries analytical articles on annual and longer term developments in labor force, employment, and unemployment; employee compensation and collective bargaining; prices; productivity; international comparisons; and injury and illness data.

Symbols

n.e.c. = not elsewhere classified.

n.e.s. = not elsewhere specified.

p = preliminary. To increase the timeliness of some series, preliminary figures are issued based on representative but incomplete returns.

r = revised. Generally, this revision reflects the availability of later data, but also may reflect other adjustments.

Comparative Indicators

(Tables 1–3)

Comparative indicators tables provide an overview and comparison of major BLS statistical series. Consequently, although many of the included series are available monthly, all measures in these comparative tables are presented quarterly and annually.

Labor market indicators include employment measures from two major surveys and information on rates of change in compensation provided by the Employment Cost Index (ECI) program. The labor force participation rate, the employment-population ratio, and unemployment rates for major demographic groups based on the Current Population (“household”) Survey are presented, while measures of employment and average weekly hours by major industry sector are given using nonfarm payroll data. The Employment Cost Index (compensation), by major sector and by bargaining status, is chosen from a variety of BLS compensation and wage measures because it provides a comprehensive measure of employer costs for hiring labor, not just outlays for wages, and it is not affected by employment shifts among occupations and industries.

Data on **changes in compensation, prices, and productivity** are presented in table 2. Measures of rates of change of compensation and wages from the Employment Cost Index

program are provided for all civilian nonfarm workers (excluding Federal and household workers) and for all private nonfarm workers. Measures of changes in consumer prices for all urban consumers; producer prices by stage of processing; overall prices by stage of processing; and overall export and import price indexes are given. Measures of productivity (output per hour of all persons) are provided for major sectors.

Alternative measures of wage and compensation rates of change, which reflect the overall trend in labor costs, are summarized in table 3. Differences in concepts and scope, related to the specific purposes of the series, contribute to the variation in changes among the individual measures.

Notes on the data

Definitions of each series and notes on the data are contained in later sections of these notes describing each set of data.

Employment and Unemployment Data

(Tables 1; 4–29)

Household survey data

Description of the series

Employment data in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 60,000 households selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

Definitions

Employed persons include (1) all those who worked for pay any time during the week which includes the 12th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding 4 weeks. Persons who did not look for work

because they were on layoff are also counted among the unemployed. **The unemployment rate** represents the number unemployed as a percent of the civilian labor force.

The **civilian labor force** consists of all employed or unemployed persons in the civilian noninstitutional population. Persons **not in the labor force** are those not classified as employed or unemployed. This group includes discouraged workers, defined as persons who want and are available for a job and who have looked for work sometime in the past 12 months (or since the end of their last job if they held one within the past 12 months), but are not currently looking, because they believe there are no jobs available or there are none for which they would qualify. The **civilian noninstitutional population** comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy. The **civilian labor force participation rate** is the proportion of the civilian noninstitutional population that is in the labor force. The **employment-population ratio** is employment as a percent of the civilian noninstitutional population.

Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the intercensal years. These adjustments affect the comparability of historical data. A description of these adjustments and their effect on the various data series appears in the Explanatory Notes of *Employment and Earnings*. For a discussion of changes introduced in January 2003, see “Revisions to the Current Population Survey Effective in January 2003” in the February 2003 issue of *Employment and Earnings* (available on the BLS Web site at www.bls.gov/cps/rvcps03.pdf).

Effective in January 2003, BLS began using the X-12 ARIMA seasonal adjustment program to seasonally adjust national labor force data. This program replaced the X-11 ARIMA program which had been used since January 1980. See “Revision of Seasonally Adjusted Labor Force Series in 2003,” in the February 2003 issue of *Employment and Earnings* (available on the BLS Web site at www.bls.gov/cps/cpsrs.pdf) for a discussion of the introduction of the use of X-12 ARIMA for seasonal adjustment of the labor force data and the effects that it had on the data.

At the beginning of each calendar year, historical seasonally adjusted data usually are revised, and projected seasonal adjustment factors are calculated for use during the January–June period. The historical season-

ally adjusted data usually are revised for only the most recent 5 years. In July, new seasonal adjustment factors, which incorporate the experience through June, are produced for the July–December period, but no revisions are made in the historical data.

FOR ADDITIONAL INFORMATION on national household survey data, contact the Division of Labor Force Statistics: (202) 691–6378.

Establishment survey data

Description of the series

Employment, hours, and earnings data in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by about 160,000 businesses and government agencies, which represent approximately 400,000 individual worksites and represent all industries except agriculture. The active CES sample covers approximately one-third of all nonfarm payroll workers. Industries are classified in accordance with the 2007 North American Industry Classification System. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

Definitions

An **establishment** is an economic unit which produces goods or services (such as a factory or store) at a single location and is engaged in one type of economic activity.

Employed persons are all persons who received pay (including holiday and sick pay) for any part of the payroll period including the 12th day of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in the goods-producing industries cover employees, up through the level of working supervisors, who engage directly in the manufacture or construction of the establishment's product. In private service-providing industries, data are collected for nonsupervisory workers, which include most employees except those in executive, managerial, and supervisory posi-

tions. Those workers mentioned in tables 11–16 include production workers in manufacturing and natural resources and mining; construction workers in construction; and nonsupervisory workers in all private service-providing industries. Production and nonsupervisory workers account for about four-fifths of the total employment on private nonagricultural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. **Real earnings** are earnings adjusted to reflect the effects of changes in consumer prices. The deflator for this series is derived from the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W).

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received, and are different from standard or scheduled hours. **Overtime hours** represent the portion of average weekly hours which was in excess of regular hours and for which overtime premiums were paid.

The **Diffusion Index** represents the percent of industries in which employment was rising over the indicated period, plus one-half of the industries with unchanged employment; 50 percent indicates an equal balance between industries with increasing and decreasing employment. In line with Bureau practice, data for the 1-, 3-, and 6-month spans are seasonally adjusted, while those for the 12-month span are unadjusted. Table 17 provides an index on private nonfarm employment based on 278 industries, and a manufacturing index based on 84 industries. These indexes are useful for measuring the dispersion of economic gains or losses and are also economic indicators.

Notes on the data

With the release of data for January 2010, the CES program introduced its annual revision of national estimates of employment, hours, and earnings from the monthly survey of nonfarm establishments. Each year, the CES survey realigns its sample-based estimates to incorporate universe counts of employment—a process known as benchmarking. Comprehensive counts of employment, or benchmarks, are derived primarily from unemployment insurance (UI) tax reports that nearly all employers are required to file with State Workforce Agencies. With the release in June 2003, CES completed the transition from its original quota sample design to a

probability-based sample design. The industry-coding update included reconstruction of historical estimates in order to preserve time series for data users. Normally 5 years of seasonally adjusted data are revised with each benchmark revision. However, with this release, the entire new time series history for all CES data series were re-seasonally adjusted due to the NAICS conversion, which resulted in the revision of all CES time series.

Also in June 2003, the CES program introduced concurrent seasonal adjustment for the national establishment data. Under this methodology, the first preliminary estimates for the current reference month and the revised estimates for the 2 prior months will be updated with concurrent factors with each new release of data. Concurrent seasonal adjustment incorporates all available data, including first preliminary estimates for the most current month, in the adjustment process. For additional information on all of the changes introduced in June 2003, see the June 2003 issue of *Employment and Earnings* and “Recent changes in the national Current Employment Statistics survey,” *Monthly Labor Review*, June 2003, pp. 3–13.

Revisions in State data (table 11) occurred with the publication of January 2003 data. For information on the revisions for the State data, see the March and May 2003 issues of *Employment and Earnings*, and “Recent changes in the State and Metropolitan Area CES survey,” *Monthly Labor Review*, June 2003, pp. 14–19.

Beginning in June 1996, the BLS uses the X-12-ARIMA methodology to seasonally adjust establishment survey data. This procedure, developed by the Bureau of the Census, controls for the effect of varying survey intervals (also known as the 4- versus 5-week effect), thereby providing improved measurement of over-the-month changes and underlying economic trends. Revisions of data, usually for the most recent 5-year period, are made once a year coincident with the benchmark revisions.

In the establishment survey, estimates for the most recent 2 months are based on incomplete returns and are published as preliminary in the tables (12–17 in the *Review*). When all returns have been received, the estimates are revised and published as “final” (prior to any benchmark revisions) in the third month of their appearance. Thus, December data are published as preliminary in January and February and as final in March. For the same reasons, quarterly establishment data (table 1) are preliminary for the first 2 months of publication and final in the third month. Fourth-quarter data are pub-

lished as preliminary in January and February and as final in March.

FOR ADDITIONAL INFORMATION on establishment survey data, contact the Division of Current Employment Statistics: (202) 691-6555.

Unemployment data by State

Description of the series

Data presented in this section are obtained from the Local Area Unemployment Statistics (LAUS) program, which is conducted in cooperation with State employment security agencies.

Monthly estimates of the labor force, employment, and unemployment for States and sub-State areas are a key indicator of local economic conditions, and form the basis for determining the eligibility of an area for benefits under Federal economic assistance programs such as the Job Training Partnership Act. Seasonally adjusted unemployment rates are presented in table 10. Insofar as possible, the concepts and definitions underlying these data are those used in the national estimates obtained from the CPS.

Notes on the data

Data refer to State of residence. Monthly data for all States and the District of Columbia are derived using standardized procedures established by BLS. Once a year, estimates are revised to new population controls, usually with publication of January estimates, and benchmarked to annual average CPS levels.

FOR ADDITIONAL INFORMATION on data in this series, call (202) 691-6392 (table 10) or (202) 691-6559 (table 11).

Quarterly Census of Employment and Wages

Description of the series

Employment, wage, and establishment data in this section are derived from the quarterly tax reports submitted to State employment security agencies by private and State and local government employers subject to State unemployment insurance (UI) laws and from Federal, agencies subject to the Unemployment Compensation for Federal Employees (UCFE) program. Each quarter, State agencies edit and process the data and send the information to the Bureau of Labor Statistics.

The Quarterly Census of Employment and Wages (QCEW) data, also referred as ES-202 data, are the most complete enumeration of employment and wage information by

industry at the national, State, metropolitan area, and county levels. They have broad economic significance in evaluating labor market trends and major industry developments.

Definitions

In general, the Quarterly Census of Employment and Wages monthly employment data represent the number of **covered workers** who worked during, or received pay for, the pay period that included the 12th day of the month. **Covered private industry employment** includes most corporate officials, executives, supervisory personnel, professionals, clerical workers, wage earners, piece workers, and part-time workers. It excludes proprietors, the unincorporated self-employed, unpaid family members, and certain farm and domestic workers. Certain types of nonprofit employers, such as religious organizations, are given a choice of coverage or exclusion in a number of States. Workers in these organizations are, therefore, reported to a limited degree.

Persons on paid sick leave, paid holiday, paid vacation, and the like, are included. Persons on the payroll of more than one firm during the period are counted by each ui-subject employer if they meet the employment definition noted earlier. The employment count excludes workers who earned no wages during the entire applicable pay period because of work stoppages, temporary layoffs, illness, or unpaid vacations.

Federal employment data are based on reports of monthly employment and quarterly wages submitted each quarter to State agencies for all Federal installations with employees covered by the Unemployment Compensation for Federal Employees (UCFE) program, except for certain national security agencies, which are omitted for security reasons. Employment for all Federal agencies for any given month is based on the number of persons who worked during or received pay for the pay period that included the 12th of the month.

An **establishment** is an economic unit, such as a farm, mine, factory, or store, that produces goods or provides services. It is typically at a single physical location and engaged in one, or predominantly one, type of economic activity for which a single industrial classification may be applied. Occasionally, a single physical location encompasses two or more distinct and significant activities. Each activity should be reported as a separate establishment if separate records are kept and the various activities are classified under different NAICS industries.

Most employers have only one establishment; thus, the establishment is the

predominant reporting unit or statistical entity for reporting employment and wages data. Most employers, including State and local governments who operate more than one establishment in a State, file a Multiple Worksite Report each quarter, in addition to their quarterly ui report. The Multiple Worksite Report is used to collect separate employment and wage data for each of the employer's establishments, which are not detailed on the ui report. Some very small multi-establishment employers do not file a Multiple Worksite Report. When the total employment in an employer's secondary establishments (all establishments other than the largest) is 10 or fewer, the employer generally will file a consolidated report for all establishments. Also, some employers either cannot or will not report at the establishment level and thus aggregate establishments into one consolidated unit, or possibly several units, though not at the establishment level.

For the Federal Government, the reporting unit is the **installation**: a single location at which a department, agency, or other government body has civilian employees. Federal agencies follow slightly different criteria than do private employers when breaking down their reports by installation. They are permitted to combine as a single statewide unit: 1) all installations with 10 or fewer workers, and 2) all installations that have a combined total in the State of fewer than 50 workers. Also, when there are fewer than 25 workers in all secondary installations in a State, the secondary installations may be combined and reported with the major installation. Last, if a Federal agency has fewer than five employees in a State, the agency headquarters office (regional office, district office) serving each State may consolidate the employment and wages data for that State with the data reported to the State in which the headquarters is located. As a result of these reporting rules, the number of reporting units is always larger than the number of employers (or government agencies) but smaller than the number of actual establishments (or installations).

Data reported for the first quarter are tabulated into **size** categories ranging from worksites of very small size to those with 1,000 employees or more. The size category is determined by the establishment's March employment level. It is important to note that each establishment of a multi-establishment firm is tabulated separately into the appropriate size category. The total employment level of the reporting multi-establishment firm is not used in the size tabulation.

Covered employers in most States report total **wages** paid during the calendar quarter, regardless of when the services were performed. A few State laws, however, specify

that wages be reported for, or based on the period during which services are performed rather than the period during which compensation is paid. Under most State laws or regulations, wages include bonuses, stock options, the cash value of meals and lodging, tips and other gratuities, and, in some States, employer contributions to certain deferred compensation plans such as 401(k) plans.

Covered employer contributions for old-age, survivors, and disability insurance (OASDI), health insurance, unemployment insurance, workers' compensation, and private pension and welfare funds are not reported as wages. Employee contributions for the same purposes, however, as well as money withheld for income taxes, union dues, and so forth, are reported even though they are deducted from the worker's gross pay.

Wages of covered Federal workers represent the gross amount of all payrolls for all pay periods ending within the quarter. This includes cash allowances, the cash equivalent of any type of remuneration, severance pay, withholding taxes, and retirement deductions. Federal employee remuneration generally covers the same types of services as for workers in private industry.

Average annual wage per employee for any given industry are computed by dividing total annual wages by annual average employment. A further division by 52 yields average weekly wages per employee. Annual pay data only approximate annual earnings because an individual may not be employed by the same employer all year or may work for more than one employer at a time.

Average weekly or annual wage is affected by the ratio of full-time to part-time workers as well as the number of individuals in high-paying and low-paying occupations. When average pay levels between States and industries are compared, these factors should be taken into consideration. For example, industries characterized by high proportions of part-time workers will show average wage levels appreciably less than the weekly pay levels of regular full-time employees in these industries. The opposite effect characterizes industries with low proportions of part-time workers, or industries that typically schedule heavy weekend and overtime work. Average wage data also may be influenced by work stoppages, labor turnover rates, retroactive payments, seasonal factors, bonus payments, and so on.

Notes on the data

Beginning with the release of data for 2007, publications presenting data from the Covered Employment and Wages program have

switched to the 2007 version of the North American Industry Classification System (NAICS) as the basis for the assignment and tabulation of economic data by industry. NAICS is the product of a cooperative effort on the part of the statistical agencies of the United States, Canada, and Mexico. Due to difference in NAICS and Standard Industrial Classification (SIC) structures, industry data for 2001 is not comparable to the SIC-based data for earlier years.

Effective January 2001, the program began assigning Indian Tribal Councils and related establishments to local government ownership. This BLS action was in response to a change in Federal law dealing with the way Indian Tribes are treated under the Federal Unemployment Tax Act. This law requires federally recognized Indian Tribes to be treated similarly to State and local governments. In the past, the Covered Employment and Wage (CEW) program coded Indian Tribal Councils and related establishments in the private sector. As a result of the new law, CEW data reflects significant shifts in employment and wages between the private sector and local government from 2000 to 2001. Data also reflect industry changes. Those accounts previously assigned to civic and social organizations were assigned to tribal governments. There were no required industry changes for related establishments owned by these Tribal Councils. These tribal business establishments continued to be coded according to the economic activity of that entity.

To insure the highest possible quality of data, State employment security agencies verify with employers and update, if necessary, the industry, location, and ownership classification of all establishments on a 3-year cycle. Changes in establishment classification codes resulting from the verification process are introduced with the data reported for the first quarter of the year. Changes resulting from improved employer reporting also are introduced in the first quarter. For these reasons, some data, especially at more detailed geographic levels, may not be strictly comparable with earlier years.

County definitions are assigned according to Federal Information Processing Standards Publications as issued by the National Institute of Standards and Technology. Areas shown as counties include those designated as independent cities in some jurisdictions and, in Alaska, those areas designated by the Census Bureau where counties have not been created. County data also are presented for the New England States for comparative purposes, even though townships are the more common designation used in New England (and New Jersey).

The Office of Management and Budget (OMB) defines metropolitan areas for use in Federal statistical activities and updates these definitions as needed. Data in this table use metropolitan area criteria established by OMB in definitions issued June 30, 1999 (OMB Bulletin No. 99-04). These definitions reflect information obtained from the 1990 Decennial Census and the 1998 U.S. Census Bureau population estimate. A complete list of metropolitan area definitions is available from the National Technical Information Service (NTIS), Document Sales, 5205 Port Royal Road, Springfield, Va. 22161, telephone 1-800-553-6847.

OMB defines metropolitan areas in terms of entire counties, except in the six New England States where they are defined in terms of cities and towns. New England data in this table, however, are based on a county concept defined by OMB as New England County Metropolitan Areas (NECMA) because county-level data are the most detailed available from the Quarterly Census of Employment and Wages. The NECMA is a county-based alternative to the city- and town-based metropolitan areas in New England. The NECMA for a Metropolitan Statistical Area (MSA) include: (1) the county containing the first-named city in that MSA title (this county may include the first-named cities of other MSA, and (2) each additional county having at least half its population in the MSA in which first-named cities are in the county identified in step 1. The NECMA is officially defined areas that are meant to be used by statistical programs that cannot use the regular metropolitan area definitions in New England.

FOR ADDITIONAL INFORMATION on the covered employment and wage data, contact the Division of Administrative Statistics and Labor Turnover at (202) 691-6567.

Job Openings and Labor Turnover Survey

Description of the series

Data for the **Job Openings and Labor Turnover Survey** (JOLTS) are collected and compiled from a sample of 16,000 business establishments. Each month, data are collected for total employment, job openings, hires, quits, layoffs and discharges, and other separations. The JOLTS program covers all private nonfarm establishments such as factories, offices, and stores, as well as Federal, State, and local government entities in the 50 States and the District of Columbia. The JOLTS sample design is a random sample drawn from a universe of more than eight mil-

lion establishments compiled as part of the operations of the Quarterly Census of Employment and Wages, or QCEW, program. This program includes all employers subject to State unemployment insurance (UI) laws and Federal agencies subject to Unemployment Compensation for Federal Employees (UCFE).

The sampling frame is stratified by ownership, region, industry sector, and size class. Large firms fall into the sample with virtual certainty. JOLTS total employment estimates are controlled to the employment estimates of the Current Employment Statistics (CES) survey. A ratio of CES to JOLTS employment is used to adjust the levels for all other JOLTS data elements. Rates then are computed from the adjusted levels.

The monthly JOLTS data series begin with December 2000. Not seasonally adjusted data on job openings, hires, total separations, quits, layoffs and discharges, and other separations levels and rates are available for the total nonfarm sector, 16 private industry divisions and 2 government divisions based on the North American Industry Classification System (NAICS), and four geographic regions. Seasonally adjusted data on job openings, hires, total separations, and quits levels and rates are available for the total nonfarm sector, selected industry sectors, and four geographic regions.

Definitions

Establishments submit **job openings** information for the last business day of the reference month. A job opening requires that (1) a specific position exists and there is work available for that position; and (2) work could start within 30 days regardless of whether a suitable candidate is found; and (3) the employer is actively recruiting from outside the establishment to fill the position. Included are full-time, part-time, permanent, short-term, and seasonal openings. Active recruiting means that the establishment is taking steps to fill a position by advertising in newspapers or on the Internet, posting help-wanted signs, accepting applications, or using other similar methods.

Jobs to be filled only by internal transfers, promotions, demotions, or recall from layoffs are excluded. Also excluded are jobs with start dates more than 30 days in the future, jobs for which employees have been hired but have not yet reported for work, and jobs to be filled by employees of temporary help agencies, employee leasing companies, outside contractors, or consultants. The job openings rate is computed by dividing the number of job openings by the sum of employment and job openings, and multiplying that quotient

by 100.

Hires are the total number of additions to the payroll occurring at any time during the reference month, including both new and rehired employees and full-time and part-time, permanent, short-term and seasonal employees, employees recalled to the location after a layoff lasting more than 7 days, on-call or intermittent employees who returned to work after having been formally separated, and transfers from other locations. The hires count does not include transfers or promotions within the reporting site, employees returning from strike, employees of temporary help agencies or employee leasing companies, outside contractors, or consultants. The hires rate is computed by dividing the number of hires by employment, and multiplying that quotient by 100.

Separations are the total number of terminations of employment occurring at any time during the reference month, and are reported by type of separation—quits, layoffs and discharges, and other separations. Quits are voluntary separations by employees (except for retirements, which are reported as other separations). Layoffs and discharges are involuntary separations initiated by the employer and include layoffs with no intent to rehire, formal layoffs lasting or expected to last more than 7 days, discharges resulting from mergers, downsizing, or closings, firings or other discharges for cause, terminations of permanent or short-term employees, and terminations of seasonal employees. Other separations include retirements, transfers to other locations, deaths, and separations due to disability. Separations do not include transfers within the same location or employees on strike.

The separations rate is computed by dividing the number of separations by employment, and multiplying that quotient by 100. The quits, layoffs and discharges, and other separations rates are computed similarly, dividing the number by employment and multiplying by 100.

Notes on the data

The JOLTS data series on job openings, hires, and separations are relatively new. The full sample is divided into panels, with one panel enrolled each month. A full complement of panels for the original data series based on the 1987 Standard Industrial Classification (SIC) system was not completely enrolled in the survey until January 2002. The supplemental panels of establishments needed to create NAICS estimates were not completely enrolled until May 2003. The data collected up until those points are from less than a

full sample. Therefore, estimates from earlier months should be used with caution, as fewer sampled units were reporting data at that time.

In March 2002, BLS procedures for collecting hires and separations data were revised to address possible underreporting. As a result, JOLTS hires and separations estimates for months prior to March 2002 may not be comparable with estimates for March 2002 and later.

The Federal Government reorganization that involved transferring approximately 180,000 employees to the new Department of Homeland Security is not reflected in the JOLTS hires and separations estimates for the Federal Government. The Office of Personnel Management's record shows these transfers were completed in March 2003. The inclusion of transfers in the JOLTS definitions of hires and separations is intended to cover ongoing movements of workers between establishments. The Department of Homeland Security reorganization was a massive one-time event, and the inclusion of these intergovernmental transfers would distort the Federal Government time series.

Data users should note that seasonal adjustment of the JOLTS series is conducted with fewer data observations than is customary. The historical data, therefore, may be subject to larger than normal revisions. Because the seasonal patterns in economic data series typically emerge over time, the standard use of moving averages as seasonal filters to capture these effects requires longer series than are currently available. As a result, the stable seasonal filter option is used in the seasonal adjustment of the JOLTS data. When calculating seasonal factors, this filter takes an average for each calendar month after detrending the series. The stable seasonal filter assumes that the seasonal factors are fixed; a necessary assumption until sufficient data are available. When the stable seasonal filter is no longer needed, other program features also may be introduced, such as outlier adjustment and extended diagnostic testing. Additionally, it is expected that more series, such as layoffs and discharges and additional industries, may be seasonally adjusted when more data are available.

JOLTS hires and separations estimates cannot be used to exactly explain net changes in payroll employment. Some reasons why it is problematic to compare changes in payroll employment with JOLTS hires and separations, especially on a monthly basis, are: (1) the reference period for payroll employment is the pay period including the 12th of the month, while the reference period for hires and separations is the calendar month; and (2) payroll employment can vary from month

to month simply because part-time and on-call workers may not always work during the pay period that includes the 12th of the month. Additionally, research has found that some reporters systematically underreport separations relative to hires due to a number of factors, including the nature of their payroll systems and practices. The shortfall appears to be about 2 percent or less over a 12-month period.

FOR ADDITIONAL INFORMATION on the Job Openings and Labor Turnover Survey, contact the Division of Administrative Statistics and Labor Turnover at (202) 961-5870.

Compensation and Wage Data

(Tables 1-3; 30-37)

The National Compensation Survey (NCS) produces a variety of compensation data. These include: The Employment Cost Index (ECI) and NCS benefit measures of the incidence and provisions of selected employee benefit plans. Selected samples of these measures appear in the following tables. NCS also compiles data on occupational wages and the Employer Costs for Employee Compensation (ECEC).

Employment Cost Index

Description of the series

The **Employment Cost Index** (ECI) is a quarterly measure of the rate of change in compensation per hour worked and includes wages, salaries, and employer costs of employee benefits. It is a Laspeyres Index that uses fixed employment weights to measure change in labor costs free from the influence of employment shifts among occupations and industries.

The ECI provides data for the civilian economy, which includes the total private nonfarm economy excluding private households, and the public sector excluding the Federal government. Data are collected each quarter for the pay period including the 12th day of March, June, September, and December.

Sample establishments are classified by industry categories based on the 2007 North American Classification System (NAICS). Within a sample establishment, specific job categories are selected and classified into about 800 occupations according to the 2000 Standard Occupational Classification (SOC) System. Individual occupations are combined to represent one of ten intermediate

aggregations, such as professional and related occupations, or one of five higher level aggregations, such as management, professional, and related occupations.

Fixed employment weights are used each quarter to calculate the most aggregate series—civilian, private, and State and local government. These fixed weights are also used to derive all of the industry and occupational series indexes. Beginning with the March 2006 estimates, 2002 fixed employment weights from the Bureau's Occupational Employment Statistics survey were introduced. From March 1995 to December 2005, 1990 employment counts were used. These fixed weights ensure that changes in these indexes reflect only changes in compensation, not employment shifts among industries or occupations with different levels of wages and compensation. For the series based on bargaining status, census region and division, and metropolitan area status, fixed employment data are not available. The employment weights are reallocated within these series each quarter based on the current ECI sample. The indexes for these series, consequently, are not strictly comparable with those for aggregate, occupational, and industry series.

Definitions

Total compensation costs include wages, salaries, and the employer's costs for employee benefits.

Wages and salaries consist of earnings before payroll deductions, including production bonuses, incentive earnings, commissions, and cost-of-living adjustments.

Benefits include the cost to employers for paid leave, supplemental pay (including nonproduction bonuses), insurance, retirement and savings plans, and legally required benefits (such as Social Security, workers' compensation, and unemployment insurance).

Excluded from wages and salaries and employee benefits are such items as payment-in-kind, free room and board, and tips.

Notes on the data

The ECI data in these tables reflect the conversion to the 2002 North American Industry Classification System (NAICS) and the 2000 Standard Occupational Classification (SOC) system. The NAICS and SOC data shown prior to 2006 are for informational purposes only. ECI series based on NAICS and SOC became the official BLS estimates starting in March 2006.

The ECI for changes in wages and salaries in the private nonfarm economy was pub-

lished beginning in 1975. Changes in total compensation cost—wages and salaries and benefits combined—were published beginning in 1980. The series of changes in wages and salaries and for total compensation in the State and local government sector and in the civilian nonfarm economy (excluding Federal employees) were published beginning in 1981. Historical indexes (December 2005=100) are available on the Internet: www.bls.gov/ect/

ADDITIONAL INFORMATION on the Employment Cost Index is available at www.bls.gov/ncs/ect/home.htm or by telephone at (202) 691-6199.

National Compensation Survey Benefit Measures

Description of the series

NCS benefit measures of employee benefits are published in two separate reports. The annual summary provides data on the incidence of (access to and participation in) selected benefits and provisions of paid holidays and vacations, life insurance plans, and other selected benefit programs. Data on percentages of establishments offering major employee benefits, and on the employer and employee shares of contributions to medical care premiums also are presented. Selected benefit data appear in the following tables. A second publication, published later, contains more detailed information about health and retirement plans.

Definitions

Employer-provided benefits are benefits that are financed either wholly or partly by the employer. They may be sponsored by a union or other third party, as long as there is some employer financing. However, some benefits that are fully paid for by the employee also are included. For example, long-term care insurance paid entirely by the employee are included because the guarantee of insurability and availability at group premium rates are considered a benefit.

Employees are considered as having **access** to a benefit plan if it is available for their use. For example, if an employee is permitted to participate in a medical care plan offered by the employer, but the employee declines to do so, he or she is placed in the category with those having access to medical care.

Employees in contributory plans are considered as **participating** in an insurance or retirement plan if they have paid required contributions and fulfilled any applicable

service requirement. Employees in noncontributory plans are counted as participating regardless of whether they have fulfilled the service requirements.

Defined benefit pension plans use predetermined formulas to calculate a retirement benefit (if any), and obligate the employer to provide those benefits. Benefits are generally based on salary, years of service, or both.

Defined contribution plans generally specify the level of employer and employee contributions to a plan, but not the formula for determining eventual benefits. Instead, individual accounts are set up for participants, and benefits are based on amounts credited to these accounts.

Tax-deferred savings plans are a type of defined contribution plan that allow participants to contribute a portion of their salary to an employer-sponsored plan and defer income taxes until withdrawal.

Flexible benefit plans allow employees to choose among several benefits, such as life insurance, medical care, and vacation days, and among several levels of coverage within a given benefit.

Notes on the data

ADDITIONAL INFORMATION ON THE NCS benefit measures is available at www.bls.gov/ncs/ebs/home.htm or by telephone at (202) 691-6199.

Work stoppages

Description of the series

Data on work stoppages measure the number and duration of major strikes or lockouts (involving 1,000 workers or more) occurring during the month (or year), the number of workers involved, and the amount of work time lost because of stoppage. These data are presented in table 37.

Data are largely from a variety of published sources and cover only establishments directly involved in a stoppage. They do not measure the indirect or secondary effect of stoppages on other establishments whose employees are idle owing to material shortages or lack of service.

Definitions

Number of stoppages: The number of strikes and lockouts involving 1,000 workers or more and lasting a full shift or longer.

Workers involved: The number of workers directly involved in the stoppage.

Number of days idle: The aggregate number of workdays lost by workers involved

in the stoppages.

Days of idleness as a percent of estimated working time: Aggregate workdays lost as a percent of the aggregate number of standard workdays in the period multiplied by total employment in the period.

Notes on the data

This series is not comparable with the one terminated in 1981 that covered strikes involving six workers or more.

ADDITIONAL INFORMATION on work stoppages data is available at www.bls.gov/cba/home.htm or by telephone at (202) 691-6199.

Price Data

(Tables 2; 38-46)

Price data are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base period—December 2003 = 100 for many Producer Price Indexes (unless otherwise noted), 1982-84 = 100 for many Consumer Price Indexes (unless otherwise noted), and 1990 = 100 for International Price Indexes.

Consumer Price Indexes

Description of the series

The **Consumer Price Index** (CPI) is a measure of the average change in the prices paid by urban consumers for a fixed market basket of goods and services. The CPI is calculated monthly for two population groups, one consisting only of urban households whose primary source of income is derived from the employment of wage earners and clerical workers, and the other consisting of all urban households. The wage earner index (CPI-W) is a continuation of the historic index that was introduced well over a half-century ago for use in wage negotiations. As new uses were developed for the CPI in recent years, the need for a broader and more representative index became apparent. The all-urban consumer index (CPI-U), introduced in 1978, is representative of the 1993-95 buying habits of about 87 percent of the noninstitutional population of the United States at that time, compared with 32 percent represented in the CPI-W. In addition to wage earners and clerical workers, the CPI-U covers professional, managerial, and technical workers, the self-employed, short-term workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctors' and dentists' fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items are kept essentially unchanged between major revisions so that only price changes will be measured. All taxes directly associated with the purchase and use of items are included in the index.

Data collected from more than 23,000 retail establishments and 5,800 housing units in 87 urban areas across the country are used to develop the "U.S. city average." Separate estimates for 14 major urban centers are presented in table 39. The areas listed are as indicated in footnote 1 to the table. The area indexes measure only the average change in prices for each area since the base period, and do not indicate differences in the level of prices among cities.

Notes on the data

In January 1983, the Bureau changed the way in which homeownership costs are measured for the CPI-U. A rental equivalence method replaced the asset-price approach to homeownership costs for that series. In January 1985, the same change was made in the CPI-W. The central purpose of the change was to separate shelter costs from the investment component of homeownership so that the index would reflect only the cost of shelter services provided by owner-occupied homes. An updated CPI-U and CPI-W were introduced with release of the January 1987 and January 1998 data.

FOR ADDITIONAL INFORMATION, contact the Division of Prices and Price Indexes: (202) 691-7000.

Producer Price Indexes

Description of the series

Producer Price Indexes (PPI) measure average changes in prices received by domestic producers of commodities in all stages of processing. The sample used for calculating these indexes currently contains about 3,200 commodities and about 80,000 quotations per month, selected to represent the movement of prices of all commodities produced in the manufacturing; agriculture, forestry, and fishing; mining; and gas and electricity and public utilities sectors. The stage-of-processing structure of PPI organizes products by class of buyer and degree of fabrication (that is, finished goods, intermediate goods, and crude materials). The traditional commodity structure of PPI organizes products by similarity of end use or material composition. The industry and product structure of PPI organizes data in accordance with the North American Indus-

try Classification System and product codes developed by the U.S. Census Bureau.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

Since January 1992, price changes for the various commodities have been averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1987. The detailed data are aggregated to obtain indexes for stage-of-processing groupings, commodity groupings, durability-of-product groupings, and a number of special composite groups. All Producer Price Index data are subject to revision 4 months after original publication.

FOR ADDITIONAL INFORMATION, contact the Division of Industrial Prices and Price Indexes: (202) 691-7705.

International Price Indexes

Description of the series

The **International Price Program** produces monthly and quarterly export and import price indexes for nonmilitary goods and services traded between the United States and the rest of the world. The export price index provides a measure of price change for all products sold by U.S. residents to foreign buyers. ("Residents" is defined as in the national income accounts; it includes corporations, businesses, and individuals, but does not require the organizations to be U.S. owned nor the individuals to have U.S. citizenship.) The import price index provides a measure of price change for goods purchased from other countries by U.S. residents.

The product universe for both the import and export indexes includes raw materials, agricultural products, semifinished manufactures, and finished manufactures, including both capital and consumer goods. Price data for these items are collected primarily by mail questionnaire. In nearly all cases, the data are collected directly from the exporter or importer, although in a few cases, prices are obtained from other sources.

To the extent possible, the data gathered refer to prices at the U.S. border for exports and at either the foreign border or the U.S. border for imports. For nearly all products, the prices refer to transactions completed during

the first week of the month. Survey respondents are asked to indicate all discounts, allowances, and rebates applicable to the reported prices, so that the price used in the calculation of the indexes is the actual price for which the product was bought or sold.

In addition to general indexes of prices for U.S. exports and imports, indexes are also published for detailed product categories of exports and imports. These categories are defined according to the five-digit level of detail for the Bureau of Economic Analysis End-use Classification, the three-digit level for the Standard International Trade Classification (SITC), and the four-digit level of detail for the Harmonized System. Aggregate import indexes by country or region of origin are also available.

BLS publishes indexes for selected categories of internationally traded services, calculated on an international basis and on a balance-of-payments basis.

Notes on the data

The export and import price indexes are weighted indexes of the Laspeyres type. The trade weights currently used to compute both indexes relate to 2000.

Because a price index depends on the same items being priced from period to period, it is necessary to recognize when a product's specifications or terms of transaction have been modified. For this reason, the Bureau's questionnaire requests detailed descriptions of the physical and functional characteristics of the products being priced, as well as information on the number of units bought or sold, discounts, credit terms, packaging, class of buyer or seller, and so forth. When there are changes in either the specifications or terms of transaction of a product, the dollar value of each change is deleted from the total price change to obtain the "pure" change. Once this value is determined, a linking procedure is employed which allows for the continued repricing of the item.

FOR ADDITIONAL INFORMATION, contact the Division of International Prices: (202) 691-7155.

Productivity Data

(Tables 2; 47-50)

Business and major sectors

Description of the series

The productivity measures relate real output to real input. As such, they encompass a family of measures which include single-factor input measures, such as output per hour,

output per unit of labor input, or output per unit of capital input, as well as measures of multifactor productivity (output per unit of combined labor and capital inputs). The Bureau indexes show the change in output relative to changes in the various inputs. The measures cover the business, nonfarm business, manufacturing, and nonfinancial corporate sectors.

Corresponding indexes of hourly compensation, unit labor costs, unit nonlabor payments, and prices are also provided.

Definitions

Output per hour of all persons (labor productivity) is the quantity of goods and services produced per hour of labor input. **Output per unit of capital services** (capital productivity) is the quantity of goods and services produced per unit of capital services input. **Multifactor productivity** is the quantity of goods and services produced per combined inputs. For private business and private nonfarm business, inputs include labor and capital units. For manufacturing, inputs include labor, capital, energy, nonenergy materials, and purchased business services.

Compensation per hour is total compensation divided by hours at work. Total compensation equals the wages and salaries of employees plus employers' contributions for social insurance and private benefit plans, plus an estimate of these payments for the self-employed (except for nonfinancial corporations in which there are no self-employed). **Real compensation per hour** is compensation per hour deflated by the change in the Consumer Price Index for All Urban Consumers.

Unit labor costs are the labor compensation costs expended in the production of a unit of output and are derived by dividing compensation by output. **Unit nonlabor payments** include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from current-dollar value of output and dividing by output.

Unit nonlabor costs contain all the components of unit nonlabor payments except unit profits.

Unit profits include corporate profits with inventory valuation and capital consumption adjustments per unit of output.

Hours of all persons are the total hours at work of payroll workers, self-employed persons, and unpaid family workers.

Labor inputs are hours of all persons adjusted for the effects of changes in the education and experience of the labor force.

Capital services are the flow of services from the capital stock used in production. It

is developed from measures of the net stock of physical assets—equipment, structures, land, and inventories—weighted by rental prices for each type of asset.

Combined units of labor and capital inputs are derived by combining changes in labor and capital input with weights which represent each component's share of total cost. Combined units of labor, capital, energy, materials, and purchased business services are similarly derived by combining changes in each input with weights that represent each input's share of total costs. The indexes for each input and for combined units are based on changing weights which are averages of the shares in the current and preceding year (the Tornquist index-number formula).

Notes on the data

Business sector output is an annually-weighted index constructed by excluding from real gross domestic product (GDP) the following outputs: general government, nonprofit institutions, paid employees of private households, and the rental value of owner-occupied dwellings. Nonfarm business also excludes farming. Private business and private nonfarm business further exclude government enterprises. The measures are supplied by the U.S. Department of Commerce's Bureau of Economic Analysis. Annual estimates of manufacturing sectoral output are produced by the Bureau of Labor Statistics. Quarterly manufacturing output indexes from the Federal Reserve Board are adjusted to these annual output measures by the BLS. Compensation data are developed from data of the Bureau of Economic Analysis and the Bureau of Labor Statistics. Hours data are developed from data of the Bureau of Labor Statistics.

The productivity and associated cost measures in tables 47-50 describe the relationship between output in real terms and the labor and capital inputs involved in its production. They show the changes from period to period in the amount of goods and services produced per unit of input.

Although these measures relate output to hours and capital services, they do not measure the contributions of labor, capital, or any other specific factor of production. Rather, they reflect the joint effect of many influences, including changes in technology; shifts in the composition of the labor force; capital investment; level of output; changes in the utilization of capacity, energy, material, and research and development; the organization of production; managerial skill; and characteristics and efforts of the work force.

FOR ADDITIONAL INFORMATION on this productivity series, contact the Division of Productivity Research: (202) 691-5606.

Industry productivity measures

Description of the series

The BLS industry productivity indexes measure the relationship between output and inputs for selected industries and industry groups, and thus reflect trends in industry efficiency over time. Industry measures include labor productivity, multifactor productivity, compensation, and unit labor costs.

The industry measures differ in methodology and data sources from the productivity measures for the major sectors because the industry measures are developed independently of the National Income and Product Accounts framework used for the major sector measures.

Definitions

Output per hour is derived by dividing an index of industry output by an index of labor input. For most industries, **output** indexes are derived from data on the value of industry output adjusted for price change. For the remaining industries, output indexes are derived from data on the physical quantity of production.

The **labor input** series is based on the hours of all workers or, in the case of some transportation industries, on the number of employees. For most industries, the series consists of the hours of all employees. For some trade and services industries, the series also includes the hours of partners, proprietors, and unpaid family workers.

Unit labor costs represent the labor compensation costs per unit of output produced, and are derived by dividing an index of labor compensation by an index of output. **Labor compensation** includes payroll as well as supplemental payments, including both legally required expenditures and payments for voluntary programs.

Multifactor productivity is derived by dividing an index of industry output by an index of combined inputs consumed in producing that output. **Combined inputs** include capital, labor, and intermediate purchases. The measure of **capital input** represents the flow of services from the capital stock used in production. It is developed from measures of the net stock of physical assets—equipment, structures, land, and inventories. The measure of **intermediate purchases** is a combination of purchased materials, services,

fuels, and electricity.

Notes on the data

The industry measures are compiled from data produced by the Bureau of Labor Statistics and the Census Bureau, with additional data supplied by other government agencies, trade associations, and other sources.

FOR ADDITIONAL INFORMATION on this series, contact the Division of Industry Productivity Studies: (202) 691-5618, or visit the Web site at: www.bls.gov/lpc/home.htm

International Comparisons

(Tables 51-53)

Labor force and unemployment

Description of the series

Tables 51 and 52 present comparative measures of the labor force, employment, and unemployment adjusted to U.S. concepts for the United States, Canada, Australia, Japan, and six European countries. The Bureau adjusts the figures for these selected countries, for all known major definitional differences, to the extent that data to prepare adjustments are available. Although precise comparability may not be achieved, these adjusted figures provide a better basis for international comparisons than the figures regularly published by each country. For further information on adjustments and comparability issues, see Constance Sorrentino, "International unemployment rates: how comparable are they?" *Monthly Labor Review*, June 2000, pp. 3-20, available on the Internet at www.bls.gov/opus/mlr/2000/06/art1full.pdf.

Definitions

For the principal U.S. definitions of the labor force, employment, and unemployment, see the Notes section on Employment and Unemployment Data: Household survey data.

Notes on the data

Foreign-country data are adjusted as closely as possible to the U.S. definitions. Primary areas of adjustment address conceptual differences in upper age limits and definitions of employment and unemployment, provided that reliable data are available to make these adjustments. Adjustments are made where applicable to include employed and unemployed persons above upper age limits and to exclude active duty military

from employment figures, although a small number of career military may be included in some European countries. Adjustments are made to exclude unpaid family workers who worked fewer than 15 hours per week from employment figures; U.S. concepts do not include them in employment, whereas most foreign countries include all unpaid family workers regardless of the number of hours worked. Adjustments are made to include full-time students seeking work and available for work as unemployed when they are classified as not in the labor force.

Where possible, lower age limits are based on the age at which compulsory schooling ends in each country, rather than based on the U.S. standard of 16. Lower age limits have ranged between 13 and 16 over the years covered; currently, the lower age limits are either 15 or 16 in all 10 countries.

Some adjustments for comparability are not made because data are unavailable for adjustment purposes. For example, no adjustments to unemployment are usually made for deviations from U.S. concepts in the treatment of persons waiting to start a new job or passive job seekers. These conceptual differences have little impact on the measures. Furthermore, BLS studies have concluded that no adjustments should be made for persons on layoff who are counted as employed in some countries because of their strong job attachment as evidenced by, for example, payment of salary or the existence of a recall date. In the United States, persons on layoff have weaker job attachment and are classified as unemployed.

The annual labor force measures are obtained from monthly, quarterly, or continuous household surveys and may be calculated as averages of monthly or quarterly data. Quarterly and monthly unemployment rates are based on household surveys. For some countries, they are calculated by applying annual adjustment factors to current published data and, therefore, are less precise indicators of unemployment under U.S. concepts than the annual figures.

The labor force measures may have breaks in series over time due to changes in surveys, sources, or estimation methods. Breaks are noted in data tables.

For up-to-date information on adjustments and breaks in series, see the Introduction and Appendix B. Country Notes in *International Comparisons of Annual Labor Force Statistics, Adjusted to U.S. Concepts, 10 Countries, 1997-2009*, on the Internet at www.bls.gov/ilc/flscomparelf.htm, and the Notes for Table 1 in the monthly report *International Unemployment Rates and Employment Indexes, Seasonally Adjusted, 2008-2010*,

on the Internet at www.bls.gov/ilc/intl_unemployment_rates_monthly.htm.

Manufacturing productivity and labor costs

Description of the series

Table 53 presents comparative indexes of manufacturing output per hour (labor productivity), output, total hours, compensation per hour, and unit labor costs for 19 countries. These measures are trend comparisons—that is, series that measure changes over time—rather than level comparisons. BLS does not recommend using these series for level comparisons because of technical problems.

BLS constructs the comparative indexes from three basic aggregate measures—output, total labor hours, and total compensation. The hours and compensation measures refer to employees (wage and salary earners) in Belgium and Taiwan. For all other economies, the measures refer to all employed persons, including employees, self-employed persons, and unpaid family workers.

The data for recent years are based on the United Nations System of National Accounts 1993 (SNA 93). Manufacturing is generally defined according to the International Standard Industrial Classification (ISIC). However, the measures for France include parts of mining as well. For the United States and Canada, manufacturing is defined according to the North American Industry Classification System (NAICS 97).

Definitions

Output. For most economies, the output measures are real value added in manufacturing from national accounts. However, output for Japan prior to 1970 and for the Netherlands prior to 1960 are indexes of industrial production. The manufacturing value added measures for the United Kingdom are essentially identical to their indexes of industrial production.

For the United States, the output measure is a chain-weighted index of real value added produced by the Bureau of Economic Analysis. BLS uses this series here to preserve international comparability. However, for its domestic industry measures, shown in tables 47–50 in this section, BLS uses a different output measures called “sectoral output,” which is gross output less intra-sector transactions.

Total hours refer to hours worked in all economies. The measures are developed from

statistics of manufacturing employment and average hours. For most other economies, recent years’ aggregate hours series are obtained from national statistical offices, usually from national accounts. However, for some economies and for earlier years, BLS calculates the aggregate hours series using employment figures published with the national accounts, or other comprehensive employment series, and data on average hours worked.

Hourly compensation is total compensation divided by total hours. Total compensation includes all payments in cash or in-kind made directly to employees plus employer expenditures for legally required insurance programs and contractual and private benefit plans. For Australia, Canada, France, Singapore, and Sweden, compensation is increased to account for important taxes on payroll or employment. For the Czech Republic, Finland, and the United Kingdom, compensation is reduced in certain years to account for subsidies.

Labor productivity is defined as real output per hour worked. Although the labor productivity measure presented in this release relates output to the hours worked of persons employed in manufacturing, it does not measure the specific contributions of labor as a single factor of production. Rather, it reflects the joint effects of many influences, including new technology, capital investment, capacity utilization, energy use, and managerial skills, as well as the skills and efforts of the workforce.

Unit labor costs are defined as the cost of labor input required to produce one unit of output. They are computed as compensation in nominal terms divided by real output.

Notes on the data

The measures for recent years may be based on current indicators of manufacturing output (such as industrial production indexes), employment, average hours, and hourly compensation until national accounts and other statistics used for the long-term measures become available. For more in-depth information on sources and methods, see <http://www.bls.gov/news.release/prod4.toc.htm>.

FOR ADDITIONAL INFORMATION on international comparisons, contact the Division of International Labor Comparisons: (202) 691-5654 or ilchelp@bls.gov.

Occupational Injury and Illness Data

(Tables 54–55)

Survey of Occupational Injuries and Illnesses

Description of the series

The Survey of Occupational Injuries and Illnesses collects data from employers about their workers’ job-related nonfatal injuries and illnesses. The information that employers provide is based on records that they maintain under the Occupational Safety and Health Act of 1970. Self-employed individuals, farms with fewer than 11 employees, employers regulated by other Federal safety and health laws, and Federal, State, and local government agencies are excluded from the survey.

The survey is a Federal-State cooperative program with an independent sample selected for each participating State. A stratified random sample with a Neyman allocation is selected to represent all private industries in the State. The survey is stratified by Standard Industrial Classification and size of employment.

Definitions

Under the Occupational Safety and Health Act, employers maintain records of nonfatal work-related injuries and illnesses that involve one or more of the following: loss of consciousness, restriction of work or motion, transfer to another job, or medical treatment other than first aid.

Occupational injury is any injury such as a cut, fracture, sprain, or amputation that results from a work-related event or a single, instantaneous exposure in the work environment.

Occupational illness is an abnormal condition or disorder, other than one resulting from an occupational injury, caused by exposure to factors associated with employment. It includes acute and chronic illnesses or disease which may be caused by inhalation, absorption, ingestion, or direct contact.

Lost workday injuries and illnesses are cases that involve days away from work, or days of restricted work activity, or both.

Lost workdays include the number of workdays (consecutive or not) on which the employee was either away from work or at work in some restricted capacity, or both, because of an occupational injury or illness. BLS measures of the number and incidence rate of lost workdays were discontinued beginning with the 1993 survey. The number of days away from work or days of restricted work activity does not include the day of injury or onset of illness or any days on which the employee would not have worked, such as a Federal holiday, even though able to work.

Incidence rates are computed as the number of injuries and/or illnesses or lost work days per 100 full-time workers.

Notes on the data

The definitions of occupational injuries and illnesses are from *Recordkeeping Guidelines for Occupational Injuries and Illnesses* (U.S. Department of Labor, Bureau of Labor Statistics, September 1986).

Estimates are made for industries and employment size classes for total recordable cases, lost workday cases, days away from work cases, and nonfatal cases without lost workdays. These data also are shown separately for injuries. Illness data are available for seven categories: occupational skin diseases or disorders, dust diseases of the lungs, respiratory conditions due to toxic agents, poisoning (systemic effects of toxic agents), disorders due to physical agents (other than toxic materials), disorders associated with repeated trauma, and all other occupational illnesses.

The survey continues to measure the number of new work-related illness cases which are recognized, diagnosed, and reported during the year. Some conditions, for example, long-term latent illnesses caused by exposure to carcinogens, often are difficult to relate to the workplace and are not adequately recognized and reported. These long-term latent illnesses are believed to be understated in the survey's illness measure. In contrast, the overwhelming majority of the reported new illnesses are those which are easier to directly relate to workplace activity (for example, contact dermatitis and carpal tunnel syndrome).

Most of the estimates are in the form of incidence rates, defined as the number of injuries and illnesses per 100 equivalent full-time workers. For this purpose, 200,000 employee hours represent 100 employee years (2,000 hours per employee). Full detail on the available measures is presented in the annual bulletin, *Occupational Injuries and*

Illnesses: Counts, Rates, and Characteristics.

Comparable data for more than 40 States and territories are available from the BLS Office of Safety, Health and Working Conditions. Many of these States publish data on State and local government employees in addition to private industry data.

Mining and railroad data are furnished to BLS by the Mine Safety and Health Administration and the Federal Railroad Administration. Data from these organizations are included in both the national and State data published annually.

With the 1992 survey, BLS began publishing details on serious, nonfatal incidents resulting in days away from work. Included are some major characteristics of the injured and ill workers, such as occupation, age, gender, race, and length of service, as well as the circumstances of their injuries and illnesses (nature of the disabling condition, part of body affected, event and exposure, and the source directly producing the condition). In general, these data are available nationwide for detailed industries and for individual States at more aggregated industry levels.

FOR ADDITIONAL INFORMATION on occupational injuries and illnesses, contact the Office of Occupational Safety, Health and Working Conditions at (202) 691-6180, or access the Internet at: www.bls.gov/iif/.

Census of Fatal Occupational Injuries

The Census of Fatal Occupational Injuries compiles a complete roster of fatal job-related injuries, including detailed data about the fatally injured workers and the fatal events. The program collects and cross checks fatality information from multiple sources, including death certificates, State and Federal workers' compensation reports, Occupational Safety and Health Administration and Mine Safety and Health Administration records, medical examiner and autopsy reports, media ac-

counts, State motor vehicle fatality records, and follow-up questionnaires to employers.

In addition to private wage and salary workers, the self-employed, family members, and Federal, State, and local government workers are covered by the program. To be included in the fatality census, the decedent must have been employed (that is working for pay, compensation, or profit) at the time of the event, engaged in a legal work activity, or present at the site of the incident as a requirement of his or her job.

Definition

A fatal work injury is any intentional or unintentional wound or damage to the body resulting in death from acute exposure to energy, such as heat or electricity, or kinetic energy from a crash, or from the absence of such essentials as heat or oxygen caused by a specific event or incident or series of events within a single workday or shift. Fatalities that occur during a person's commute to or from work are excluded from the census, as well as work-related illnesses, which can be difficult to identify due to long latency periods.

Notes on the data

Twenty-eight data elements are collected, coded, and tabulated in the fatality program, including information about the fatally injured worker, the fatal incident, and the machinery or equipment involved. Summary worker demographic data and event characteristics are included in a national news release that is available about 8 months after the end of the reference year. The Census of Fatal Occupational Injuries was initiated in 1992 as a joint Federal-State effort. Most States issue summary information at the time of the national news release.

FOR ADDITIONAL INFORMATION on the Census of Fatal Occupational Injuries contact the BLS Office of Safety, Health, and Working Conditions at (202) 691-6175, or the Internet at: www.bls.gov/iif/

¹ Quarterly data seasonally adjusted.

² Annual changes are December-to-December changes. Quarterly changes are calculated using the last month of each quarter.

³ The Employment Cost Index data reflect the conversion to the 2002 North American Classification System (NAICS) and the 2000 Standard Occupational Classification (SOC) system. The NAICS and SOC data shown prior to 2006 are for informational purposes only. Series based on NAICS and SOC became the official BLS estimates starting in March 2006.

⁴ Excludes Federal and private household workers.

⁵ Goods-producing industries include mining, construction, and manufacturing. Service-providing industries include all other private sector industries.

NOTE: Beginning in January 2003, household survey data reflect revised population controls. Nonfarm data reflect the conversion to the 2002 version of the North American Industry Classification System (NAICS), replacing the Standard Industrial Classification (SIC) system. NAICS-based data by industry are not comparable with SIC-based data.

2. Annual and quarterly percent changes in compensation, prices, and productivity

¹ Annual changes are December-to-December changes. Quarterly changes are calculated using the last month of each quarter. Compensation and price data are not seasonally adjusted, and the price data are not compounded.

² Excludes Federal and private household workers.

³ The Employment Cost Index data reflect the conversion to the 2002 North American Classification System (NAICS) and the 2000 Standard Occupational Classification (SOC) system. The NAICS and SOC data shown prior to 2006 are for informational purposes

only. Series based on NAICS and SOC became the official BLS estimates starting in March 2006.

⁴ Annual rates of change are computed by comparing annual averages. Quarterly percent changes reflect annual rates of change in quarterly indexes. The data are seasonally adjusted.

⁵ Output per hour of all employees.

¹ The population figures are not seasonally adjusted.

² Civilian employment as a percent of the civilian noninstitutional population.

³ Beginning in 2003, persons who selected this race group only; persons who selected more than one race group are not included. Prior to 2003, persons who reported more than one race were included in the group they identified as the main race.

NOTE: Estimates for the above race groups (white and black or African American) do not sum to totals because data are not presented for all races. In addition, persons whose ethnicity is identified as Hispanic or Latino may be of any race and, therefore, are classified by ethnicity as well as by race. Beginning in January 2003, data reflect revised population controls used in the household survey.

¹ Includes workers covered by Unemployment Insurance (UI) and Unemployment Compensation for Federal Employees (UCFE) programs.

² Includes data for Metropolitan Statistical Areas (MSA) as defined by OMB Bulletin No. 04-03 as of February 18, 2004.

³ Each year's total is based on the MSA definition for the specific year. Annual changes include differences resulting from changes in MSA definitions.

⁴ Totals do not include the six MSAs within Puerto Rico.

27. Annual data: Employment status of the population

¹ Cost (cents per hour worked) measured in the Employment Cost Index consists of wages, salaries, and employer cost of employee benefits.

² Consists of private industry workers (excluding farm and household workers) and State and local government (excluding Federal Government) workers.

³ Consists of legislative, judicial, administrative, and regulatory activities.

NOTE: The Employment Cost Index data reflect the conversion to the 2002 North American Classification System (NAICS) and the 2000 Standard Occupational Classification (SOC) system. The NAICS and SOC data shown prior to 2006 are for informational purposes only. Series based on NAICS and SOC became the official BLS estimates starting in March 2006.

¹ The 2002 North American Industry Classification System (NAICS) replaced the 1987 Standard Industrial Classification (SIC) System. Estimates for goods-producing and service-providing (formerly service-producing) industries are considered comparable. Also introduced was the 2000 Standard Occupational Classification (SOC) to replace the 1990 Census of Population system. Only service occupations are considered comparable.

² The white-collar and blue-collar occupation series were discontinued effective 2007.

³ The take-up rate is an estimate of the percentage of workers with access to a plan who participate in the plan.

Note: Where applicable, dashes indicate no employees in this category or data do not meet publication criteria.

¹ The 2002 North American Industry Classification System (NAICS) replaced the 1987 Standard Industrial Classification (SIC) System. Estimates for goods-producing and service-providing (formerly service-producing) industries are considered comparable. Also introduced was the 2000 Standard Occupational Classification (SOC) to replace the 1990 Census of Population system. Only service occupations are considered comparable.

² The white-collar and blue-collar occupation series were discontinued effective 2007.

³ The take-up rate is an estimate of the percentage of workers with access to a plan who participate in the plan.

Note: Where applicable, dashes indicate no employees in this category or data do not meet publication criteria.

36. National Compensation Survey: Percent of workers in private industry with access to selected benefits, 2003-2007

¹ Foods, fuels, and several other items priced every month in all areas; most other goods and services priced as indicated:

M—Every month.
¹—January, March, May, July, September, and November.
²—February, April, June, August, October, and December.

² Regions defined as the four Census regions.

³ Indexes on a December 1996 = 100 base.

⁴ The "North Central" region has been renamed the "Midwest" region by the Census Bureau. It is composed of the same geographic entities.

⁵ Indexes on a December 1986 = 100 base.

⁶ In addition, the following metropolitan areas are published semiannually and appear in tables 34 and 39 of the January and July issues of the *CPI Detailed*

Report: Anchorage, AK; Cincinnati, OH—KY—IN; Kansas City, MO—KS; Milwaukee—Racine, WI; Minneapolis—St. Paul, MN—WI; Pittsburgh, PA; Portland—Salem, OR—WA; St. Louis, MO—IL; San Diego, CA; Tampa—St. Petersburg—Clearwater, FL.

⁷ Indexes on a November 1996 = 100 base.

NOTE: Local area CPI indexes are byproducts of the national CPI program. Each local index has a smaller sample size and is, therefore, subject to substantially more sampling and other measurement error. As a result, local area indexes show greater volatility than the national index, although their long-term trends are similar. Therefore, the Bureau of Labor Statistics strongly urges users to consider adopting the national average CPI for use in their escalator clauses. Index applies to a month as a whole, not to any specific date. Dash indicates data not available.

40. Annual data: Consumer Price Index, U.S. city average, all items and major groups

United Kingdom.....	7.7	7.9	7.1	7.8	7.9	7.8	8.0	7.8	7.8	7.9

Dash indicates data are not available. Quarterly figures for Germany are calculated by applying an annual adjustment factor to current published data and therefore should be viewed as a less precise indicator of unemployment under U.S. concepts than the annual figures. For further qualifications and historical annual data, see the BLS report *International Comparisons of Annual Labor Force Statistics, Adjusted to U.S. Concepts, 10 Countries* (on the Internet at <http://www.bls.gov/ilc/flscompare.htm>).

For monthly unemployment rates, as well as the quarterly and annual rates published in this table, see the BLS report *International Unemployment Rates and Employment Indexes, Seasonally Adjusted* (on the Internet at http://www.bls.gov/ilc/intl_unemployment_rates_monthly.htm). Unemployment rates may differ between the two reports mentioned, because the former is updated annually, whereas the latter is updated monthly and reflects the most recent revisions in source data.

52. Annual data: employment status of the working-age population, adjusted to U.S. concepts, 10 countries

¹ Labor force as a percent of the working-age population.

² Employment as a percent of the working-age population.

³ Unemployment as a percent of the labor force.

NOTE: There are breaks in series for the United States (2003, 2004), Australia (2001), Germany (2005), the Netherlands (2003), and Sweden (2005). For further qualifications and historical annual data, see the BLS report *International*

Comparisons of Annual Labor Force Statistics, Adjusted to U.S. Concepts, 10 Countries (on the Internet at <http://www.bls.gov/ilc/flscomparelf.htm>). Unemployment rates may differ from those in the BLS report *International Unemployment Rates and Employment Indexes, Seasonally Adjusted* (on the Internet at http://www.bls.gov/intl_unemployment_rates_monthly.htm), because the former is updated annually, whereas the latter is updated monthly and reflects the most recent revisions in source data.

¹ Data for 1989 and subsequent years are based on the *Standard Industrial Classification Manual*, 1987 Edition. For this reason, they are not strictly comparable with data for the years 1985-88, which were based on the *Standard Industrial Classification Manual*, 1972 Edition, 1977 Supplement.

² Beginning with the 1992 survey, the annual survey measures only nonfatal injuries and illnesses, while past surveys covered both fatal and nonfatal incidents. To better address fatalities, a basic element of workplace safety, BLS implemented the Census of Fatal Occupational Injuries.

³ The incidence rates represent the number of injuries and illnesses or lost workdays per 100 full-time workers and were calculated as (N/EH) X 200,000, where:

N = number of injuries and illnesses or lost workdays;
EH = total hours worked by all employees during the calendar year; and
200,000 = base for 100 full-time equivalent workers (working 40 hours per week, 50 weeks per year).

⁴ Beginning with the 1993 survey, lost workday estimates will not be generated. As of 1992, BLS began generating percent distributions and the median number of days away from work by industry and for groups of workers sustaining similar work disabilities.

⁵ Excludes farms with fewer than 11 employees since 1976.

NOTE: Dash indicates data not available.

55. Fatal occupational injuries by event or exposure, 1996-2005

Event or exposure ¹	1996-2000 (average)	2001-2005 (average) ²	2005 ³	
			Number	Percent
All events	6,094	5,704	5,734	100
Transportation incidents	2,608	2,451	2,493	43

Exposure to caustic, noxious, or allergenic substances	112	114	136	2
Oxygen deficiency	92	74	59	1
Fires and explosions	196	174	159	3
Fires--unintended or uncontrolled	103	95	93	2
Explosion	92	78	65	1

¹ Based on the 1992 BLS Occupational Injury and Illness Classification Manual.

² Excludes fatalities from the Sept. 11, 2001, terrorist attacks.

³ The BLS news release of August 10, 2006, reported a total of 5,702 fatal work injuries for calendar year 2005. Since then, an additional 32 job-related fatalities were identified, bringing the total job-related fatality count for 2005 to 5,734.

NOTE: Totals for all years are revised and final. Totals for major categories may include subcategories not shown separately. Dashes indicate no data reported or data that do not meet publication criteria. N.e.c. means "not elsewhere classified."

The Relevance of Occupational Wage Leveling

by John E. Buckley
Bureau of Labor Statistics

Originally Posted: April 27, 2012

For more than 50 years, the Bureau of Labor Statistics (BLS) [National Compensation Survey \(NCS\)](#) and its predecessor surveys were a principal source of occupational wage data broken out by work level. Occupational pay data by work level provide more refined results than data rolled up to a higher aggregated level. Leveling is the process that reflects differences in duties and responsibilities within the occupation. For example, the federal government recognizes eight levels of chemists, from entry-level chemist to a chemist who may have responsibility for an entire chemical program or equivalent responsibilities.

Having data without levels for an occupation—engineers, for example—would have limited value to a large company with several hundred engineers from entry level to engineering department manager. The federal government has a 15-grade General Schedule (GS) that covers a majority of its white-collar workers. This 15-grade system was used by the NCS to develop a system to classify by level the occupational data obtained from survey respondents.

The locality pay portion of the NCS, which produced the occupational levels, was used by the designated federal authority, the presidents pay agent, to adjust federal white-collar salaries. The publication of the 2010 NCS national estimates marked the end of wage estimates based on the locality pay program. Instead, an alternative program will produce occupational levels.

This article explains the importance of producing occupational wage level data, which are collected from sampled establishments by BLS field economists. Typically, the initial data collection was conducted through personal visit to the establishments' representatives, and data were updated annually by a combination of email, regular mail, and telephone. The publication [National Compensation Survey: Occupational Earnings in the United States, 2010](#) presents published data for 10 aggregated (rolled up) levels of management occupations.¹ To illustrate, table 1 shows overall aggregated levels 9 and 12, along with data for four detailed management occupations at the same two levels.

Table 1. Mean hourly earnings in full-time management occupations, aggregated and detailed levels 9 and 12, private industry workers, National Compensation Survey, July 2010

Occupation	Level 9	Level 12	Level 12 as percent of level 9
Aggregated level	\$31.20	\$63.57	204
Finance managers	30.01	84.18	281
General and operations managers	30.83	63.38	206
Education administrators, postsecondary	29.99	81.59	272
Medical and health services managers	27.55	51.86	188

The weighted average hourly earnings rate for all level-9 management workers, \$31.20, was close to the rates for the four detailed level-9 occupations, and, lacking detailed levels, could reasonably be a proxy for the detailed occupation. However, the aggregated level 12 is not a good substitute for detailed occupational levels. Without data by level for medical and health services managers, employers relying on the aggregated rate would be paying a premium of approximately 23 percent, all other things being equal: $[(\$63.57 \div 51.86) \times 100] - 100 = 22.6$ percent. Occupational earnings by level can also indicate the career earnings path for different jobs. Table 2 shows average hourly earnings for selected level-5 (entry level), level-9 (midpoint career), and level-12 (journey level) management and professional jobs. In this example, average earnings of level-5 engineers are considerably higher than those of accountants and financial analysts at the same level. The differences in earnings are considerably narrower for level-9 professional jobs. The average hourly earnings of engineers and

accountants are not significantly different at level 12, but at this level the average earnings of financial analysts and advisors surpassed those of engineers by a significant amount.

Table 2. Mean hourly earnings in selected full-time management and professional occupations, levels 5, 9, and 12, private industry workers, National Compensation Survey, July 2010

Occupation	Level 5	Level 9	Level 12	Level 12 as percent of level 5
Accountants and auditors	\$17.93	\$29.92	\$52.27	192
Financial analysts and advisors	19.52	33.04	71.09	264
Engineers	28.00	34.36	53.16	90

As indicated by the percentage figures in the right-hand column in table 2, higher or lower earnings at the entry level do not necessarily mean that the same patterns will be sustained at higher work levels. Level-5 engineers had considerably higher earnings than the earnings of level-5 accountants and financial analysts. At level 12, however, engineers' average earnings were a modest 90 percent higher than level-5 engineers, while level-12 financial analysts' earnings were 264 percent higher than level-5 financial analysts.

The Future Of Occupational Leveling

As noted previously, with the replacement of the locality pay portion of the National Compensation Survey, no BLS program will publish occupational wage data by level. The NCS is introducing a sample design under which it will continue to collect data by occupational level, but the sample sizes will not be sufficient to produce occupational detail by level. The Bureau's [Occupational Employment Statistics \(OES\)](#) program provides annual data on employment and wages by occupation and industry for over 800 occupations and for about 400 industries throughout the nation, as well as similar data for all states and selected metropolitan areas. The occupational data are not broken out by level; however, both the NCS and the OES staff are currently researching methods to incorporate the leveling data from the NCS with the OES data by means of modeling techniques. This will result in producing more leveling data for more areas than was the case under the locality pay survey.

How Occupations Are Leveled

Before the locality pay portion of the National Compensation Survey was replaced, the Bureau's field economists evaluated each sampled job, as the data were collected, using a point-factor method to determine its work level based on related duties and responsibilities. Four factors—*knowledge, job controls and complexity, contacts* (nature and purpose), and *physical environment*—were applied to each of the sampled jobs as they were slotted into one of 15 work levels based on the total number of points attained. The Bureau's publication *National Compensation Survey: Guide for Evaluating Your Firms Jobs and Pay* provides a full description of the leveling process with examples and worksheets.²
