Public Utility Pricing, Debt Financing, and Consumer Welfare

State Taxation of Fifth District Banks
The Economic Review is produced by the Research Department of the Federal Reserve Bank of Richmond. Subscriptions are available to the public without charge. Address inquiries to Bank and Public Relations, Federal Reserve Bank of Richmond, P. O. Box 27622, Richmond, Virginia 23261. Articles may be reproduced if source is given. Please provide the Bank's Research Department with a copy of any publication in which an article is used.
The financial problems of public utilities were suddenly thrown into sharp focus earlier this spring. On April 23, the Consolidated Edison Company (serving approximately half the population of New York State) omitted its dividend for the first time in nearly 90 years. On the same day, a major private rating agency (Standard and Poor's Corporation) reduced its rating of the company's bonds from BBB to BB—a classification making them ineligible as legal investments for fiduciary financial institutions in New York State. So strained was Consolidated Edison (Con. Ed.) that it had to appeal to the State for emergency assistance. In the closing hours of this year's legislative session, a sum of $500 million of State aid was provided through the purchase of two of the Company's generating stations still under construction (on which the State must spend another $300 million to complete the projects).

In the wake of Con. Ed's difficulties, the market value of public utility stocks generally declined appreciably. Quite a few of the privately-owned firms found it difficult—if not impossible—to sell long-term debt to finance the expansion of capacity and to install pollution abatement equipment. While regulators, investment analysts, and private investors had been uneasy about utilities for some time, a number of consumer group spokesmen also broadened the discussion of the future of public utilities.

For quite a few months, some of us in the Federal Reserve System have also been concerned with the growing difficulties being encountered by public utilities. Among these difficulties, their deepening financial problems are particularly troublesome. Unless they are able to overcome these financing obstacles in the next few years, consumers are likely to bear the real costs of such failure in the form of energy shortages, much higher prices, and severe constraints on the improvement of consumer welfare.

Given this prospect, I decided to explore the subject again. Specifically, I wanted to know the nature and magnitude of the financing problem which the utilities will face over the next few years—and not simply its longer-run dimensions. I also wanted to know the extent to which the regulators of public utilities—at the Federal, State, and local levels—appreciate the scope of the financing difficulties and are responding to the need to assure a sounder financial base. To obtain insights into the way in which the regulatory process is working under present circumstances, I asked the 12 Federal Reserve Banks to make an informal survey of the situation in their Districts. The results of that canvass are reported on here. Finally, I wanted a clearer picture of the consequences for consumer welfare of the differential pricing practices generally followed by electric and gas utilities.

These issues are analyzed in some detail in the rest of this paper. The highlights can be summarized here:

In the last decade—but especially in the last year—inflation has had a severe impact on public utilities. Their fuel costs have risen beyond the expectations of the most pessimistic forecasters, and their earnings have continued to deteriorate. They have had to finance a greatly increased volume of capital investment (a sizable proportion of which was required for pollution abatement) during a period in which their cash flow was depressed, and cost of both debt and equity funds was rising.

The normally long lead time required for new construction has been lengthened further by delays necessitated by the filing of environmental impact statements. Moreover, the growth of consumer awareness has added new pressures against increases in utility rates—despite the rising costs of providing service.

Over the last few years, the ability of public utilities to raise funds in the capital market has deteriorated appreciably. A substantial number of firms are not earning enough to cover their interest costs to the extent investors normally find appealing (typically a 2-to-1 earnings-cost ratio). This means that they are effectively barred from floating long-term debt. Some utilities have also experienced difficulty in rolling over commercial paper. Consequently, a growing proportion of utilities have found it necessary to rely temporarily on short-term bank credit.

Moreover, a significant number of these firms have had their bond rating lowered or suspended. For example, the number of adverse rating actions in the first 4½ months of this year exceeds those occurring in all of 1972 and 1973.

The results of an informal survey of public utilities undertaken by the Federal Reserve Banks earlier this month suggest that the regulatory process has not been accelerated—despite the severity of the financial problems which these firms face. Of the nearly 100 utilities contacted, over 80 per cent have sought rate relief within the last year. Just under half of the requests were granted in full; another one-seventh were granted either in part or on an interim basis, and two-fifths were still pending.

The time typically required for the resolution of a request for a rate adjustment apparently has not been shortened significantly—if at all. While the time lag varies widely among the States, it averages from 9-12 months. If lags are too long, the rate adjustments are often too small.

The majority of respondents reported automatic rate adjustments for fuel costs and purchased electricity as well. In many cases, such clauses had applied to nonresidential customers for some years, and the procedure was extended to all customers recently. Nevertheless, while these clauses help somewhat in cushioning the impact of escalating fuel costs, these schemes vary considerably in the speed with which a cost increase is reflected in a rate increase.

As I weigh the financial situation faced by public utilities, I am personally convinced that their difficulties—in fact—confronted by genuine difficulties. At the same time, however, I do not believe these difficulties will lead to a parade of utilities to their respective State legislatures to seek emergency assistance—as one large company had to do in New York State. Instead, I am personally convinced that a more sympathetic—and timely—response of regulators to requests for rate adjustments will enable the vast majority of firms to cope with their problems.

On the other hand, I believe that—before too long—utilities ought to give serious attention to efforts to correct the historic pattern of pricing which favors large commercial or industrial users with lower rates than are charged residential or small commercial customers. For example, in 1972, the residential electric consumer paid over twice as much per kilowatt hour as the large commercial customer. In the same year, residential gas consumers paid a rate over 2½ times as high as the industrial consumers.

While recognizing that there are some physical efficiencies in delivering energy to large users, I believe these quantity discounts are no longer consistent with our long-run need to conserve energy resources. I personally think it would be better to replace the existing system of pricing with a structure that puts much more emphasis on peak load rate differentials for both time of day and season of the year. This scheme would have little impact on industrial users, and there would be a tendency to redistribute costs of electric use toward affluent residential users.

In the meantime, we as a society must give careful consideration to the way in which we are to allocate our scarce energy resources. Moreover, we should all accept the fact that this growing scarcity will mean higher prices for energy relative to most other items on which consumers can spend their income. In the long-run, it is better to permit these increases in real costs to be passed on to final users—rather than pretend that we can—somehow—escape the burden. Only in this way will consumer welfare be truly served in the years ahead.

Changing Perception of the Problem of Public Utilities

In October, 1964, the Federal Power Commission (FPC) released its report on the National Power Survey which it initiated in 1962. This Survey, the first comprehensive study of the electric power industry as a whole, pointed out efficient patterns of development and coordination in electric power generation among all segments of the industry which might be attainable during the 1970's. In retrospect, it exhibits the optimism which prevailed a decade ago. The report is filled with chapters such as the one entitled “A History of Industrial Growth and Cost Reductions” as well as exhortations such as “...The challenge facing the electric power industry is to continue the long-term trend of selling electricity to the consumer at steadily lower prices...”  

The concluding chapter was titled “Outlook for Cost Reductions.” However, the matter of sources of financing for the projected growth in capacity was barely discussed except to point out that the internal funds of investor-owned companies were accounting for an increasing share of the funds for capital expansion.

In 1972, the Commission issued another Power Survey report covering the period 1970-1990. The

http://fraser.stlouisfed.org/
Federal Reserve Bank of St. Louis
world as viewed in this Survey seemed different indeed from that which had been promised only a few years before. For example, the FPC now

... estimated that the recent reversal in the historical downward trend in the real cost of electric service will be carried into the future.... (Volume I, page I-19-1.)

It also observed that:

... When the first National Power Survey was published in 1964... electric power companies had little trouble raising the funds needed to modernize and expand their plant. Today this is far from the case.... (Ibid., page I-20-1.)

The recent Power Survey contained an entire chapter from the perspective of 1970 on the industry’s financing problems anticipated for the period of tremendous expansion projected for the following two decades. In general, its tone was guardedly optimistic about the industry’s ability to raise these substantial sums in the capital markets.

Unfortunately, events seem once again to have overtaken the forecasters. Within the last year, fuel costs have risen beyond the expectations of even the most pessimistic forecasters of a few years ago. Interest rates have remained high and show little prospect of falling. The rate of inflation has accelerated, and utility earnings have continued to deteriorate. The scholarly as well as the popular literature abounds with articles on the ill-health of the utility industry in general and of many companies in particular. Many firms have been forced to issue stock since earnings have been insufficient to meet the interest coverage requirements in existing bond indentures.

The sources of these problems are not difficult to isolate. Capital outlays have been substantial since 1965—a period in which investment was virtually stagnant in other sectors. Furthermore, this expansion had to be financed during a period in which the utilities’ cash flow was depressed, and the cost of both debt and equity capital was rising. As each increase becomes imbedded into the industry’s cost structure, further upward pressure on the cost of funds is exerted.† Inflation has taken its toll as well. Construction costs have risen, fuel costs have risen, and part of the rise in interest rates is attributable to an inflation premium. Costs of pollution abatement also enter into both operating and construction expenses. Clean fuels are in relatively short supply— and therefore costly—and the emission control equipment incorporated into plants is also expensive. The long construction periods for new capacity have been lengthened further by the delays caused by the required filings of environmental impact statements and the challenges of an increasingly environmentally conscious public. Finally, in addition to the lags already existing in the regulatory process, the growth of consumer awareness has added new pressures for keeping rates from rising rapidly if at all—although the consumer price index (CPI) reports increases averaging 5 per cent per year in gas and electric costs in the last two years.

Financial Developments Since 1964 The year 1965 saw the peak of popularity for utility stocks; since then price-earnings (P/E) ratios have fallen, interest rates have risen, and the financial picture of the sector has deteriorated. In 1968 and 1969, interest rates had risen sufficiently to elicit articles in one of the leading publications (Public Utilities Fortnightly—hereafter cited as P.U.F.) calling for more sophisticated and yield-conscious techniques of cash management or for the use of short-term instruments for financing in a period of high interest rates.4 The legacy of such activities is perhaps to be found in the low level of liquidity in the utility sector and in the bulge in the financing calendar in 1975 when the five-year notes of 1970 come due. Currently some observers are advocating off-balance sheet financing (leasing, primarily) as a way of making the industry’s securities more attractive to the investing public.5 Other observers, however, point out that the adoption of lease capitalization as an accounting principle by the Securities and Exchange Commission (SEC) will dissipate the advantage very rapidly.

Some of the industry’s financial problems can be traced in the statistical tables included in this paper. These tables have been assembled from a variety of sources which do not seem to possess a high degree of consistency with one another. Unfortunately, time did not permit us to engage in any elaborate attempts at reconciliation. But whatever the differences in data, they all tell essentially the same story.

Tables 1, 2, and 3 show the utility component of the principal bodies of aggregate data on sources of funds which have been incorporated into the Flow of Funds accounts compiled by the Federal Reserve Board’s staff. These are data showing the profits and cash flow series compiled by the Bureau of Eco-

† Earnings must be larger to cover the additional fixed charges, and price-earnings (P/E) ratios and the yields required to market new bond issues are also likely to increase.

nomics Analysis (BEA) in the Department of Commerce; the SEC security issue series; and the SEC Corporate Working Capital series. Tables 4, 5, and 6 are based largely on aggregate data for investor-owned gas utilities compiled by the American Gas Association and investor-owned class A and B electric utilities compiled by the FPC. Again, the focus is on sources of funds, capital outlays, and rates of return.

Both sets of data indicate a growing shortfall of internal funds relative to capital expenditures. Moreover, the problem is much more acute for electric than for gas utilities which have somewhat higher rates of return. In the case of external financing, both sets of data again point up the growing share of utilities in long-term securities offered in the capital market. When one examines liquidity ratios, it is easy to see why this volume of external financing was required quite apart from the massive capital outlays. Even more than nonfinancial business as a whole, utilities have exhibited the decline in holdings of short-term assets relative to short-term liabilities which has characterized the last 20 years. Once again the problem is more severe for electric than for gas utilities. Furthermore, much of the 1973 growth in the current assets of utilities is attributable to substantial increases in inventory book values and receivables. Bank credit and short-term securities (probably commercial paper) account for most of the even larger increase in current liabilities.

The capital structure of both electric utilities and gas utilities other than pipelines has shifted from common equity to debt over the period. However, for gas transmission companies, the reverse is true. Unfortunately, it is not possible to separate their security issues from the aggregate. Finally, interest coverage has declined—again less so for gas pipelines than for the others—and the average interest rate imbedded in the debt structure has drifted up. Not surprisingly, the net return on common equity has fallen throughout for electric utilities, risen slightly for pipelines, and fallen and then improved again for other gas utilities during the period 1964-1973.

Recent Utility Financing Problems
As indicated above, the ability of public utilities to raise funds in the capital market has deteriorated appreciably in recent years. At this point, it might be helpful to take a closer look at the extent of the deterioration.

Interest Coverage: At the end of 1971 (the latest date for which complete data are available), interest coverage ratios for electric utilities (shown in Table 7) indicated that roughly one-tenth of the companies were for all practical purposes precluded from long-term borrowing in the public market. And more recently available information suggests some general further deterioration in these ratios. Pre-tax earnings coverage of at least two times long-term interest charges appears to be the generally accepted lower limit tolerated in the market. In many cases, company mortgage indentures specifically restrict additional long-term borrowing when the pre-tax earnings fail to meet this test.8

The rating agencies also like to have a two times coverage for a Baa rating. There are exceptions, however. For example, Moody's recently gave an A rating to an electric utility with 1.75 times coverage since the low ratio did not reflect interim rate increases presently in effect and additional increases expected.

Maturing Debt: As shown in Table 8, about $8.2 billion of public utility bonds and notes will mature during the period 1974-78. Just over $1 billion is due this year, and $2.5 billion matures in 1975. Over half of the public utility debt to be refunded during 1974-78.

8 One electric utility contacted by the St. Louis Federal Reserve Bank reported such an experience. In 1972, the company had to resort to selling preferred stock and obtained long-term bank loans. After receiving rate relief, the company sold bonds in early 1974.

1 The ratio is calculated using earnings before income taxes, and the credits of interest charged to construction have been treated as other income. The interest charges include interest on long-term debt, interest on debt to associated companies, and other interest expense.

this year and next year carries coupons of less than 4.00 per cent (shown in Table 9). The implications of refunding this debt at prevailing rates (even if one assumes that current pressures in money markets might ease) are quite obvious.

Ratings: Downgrading of utility bonds has accelerated sharply in recent weeks. Even if Consolidated Edison and the 5 related companies (included in Table 10 as “rating suspended”) are excluded, the number of adverse rating actions thus far this year exceeds those occurring in all of 1972 and 1973. There have also been recent instances of lowering of municipally-owned utility ratings.

Information on downgrading of public utility commercial paper issuers is more sketchy. Moody's withdrew its rating for Consolidated Edison paper and downgraded 4 other utility issuers during April. The crucial question, however, is whether the Prime-2 and Prime-3 rated issuers are able to place new or roll-over outstanding paper. Reportedly, a number of these issuers are experiencing appreciable difficulty in doing so.

Changes in Dividends: Consolidated Edison of New York is the only notable public utility to omit a dividend this year. However, at least eight other electric utilities failed to earn their current dividend in the most recent earnings period. But they have announced “commitments to maintain dividends.”

Recent Capital Market Financing Adjustments: In the last six or seven weeks, there have been numerous instances of public utility borrowers re-vamping their financing plans to meet rapidly changing market conditions. Adjustments in plans and temporary delays in order to obtain fairly prompt accommodation in the capital markets rather than indefinite postponements seem to be the more frequent occurrence. Major utilities have reduced the size of their offerings; switched from stock issues to bond issues (following the sharp price drop in utility stocks after the Con. Ed. dividend omission); reduced maturity of issue from long-term to intermediate-term; switched from competitive to negotiated bidding—and (in at least one case) arranged alternative long-term bank financing.

c Pipeline and distribution company.

Table 11 provides figures on recent trends in common equity as a percentage of total capitalization of electric utility companies. However, while stock financing is attractive in terms of their balance sheets, this option is not currently a feasible alternative to bond financing for many of these companies since their common shares are selling below book value.

Utility Rates and the Regulatory Process

As I indicated above, I wanted to get an appreciation of the extent to which the financial problems of public utilities can be traced to the "regulatory lag" as well as to inflation. Expressed simply, the regulatory lag is the time which must elapse between an increase in costs and the permission (and ability) to recoup it. Since most rates are based on past costs rather than projected expenditures, in an inflationary environment earnings would suffer—even if the pace of the regulatory procedure were to be accelerated.

To obtain some impression of the way in which the regulatory process is currently working—as far as public utility rate adjustments are concerned—I asked the 12 Federal Reserve Banks to make an informal telephone survey in their Districts. The questions included in the inquiry were:

a. What regulatory bodies (State, local or Federal) have jurisdiction over the firm's rate applications, and is there overlapping authority?

b. Within the last year, has the firm requested a rate increase, and if so what was its disposition (including speed of decision).

c. Does the firm possess an automatic rate pass-through on changes in fuel and/or other costs?

The questions were sent to the Reserve Banks on May 7, 1974, with a response requested by May 14. As Table 12 indicates, 98 utilities were contacted. Of these companies, 42 are electric utilities, another 25 are combination gas and electric utilities, 28 are gas distribution companies, and 3 are pipelines. New England accounts for more than one-fifth of the companies surveyed; the Kansas City, Atlanta, and Richmond Districts together contribute an additional 30 per cent, and the rest is distributed over the remaining Districts.

1. Regulatory Jurisdiction. With respect to regulatory authority, no district reported any problems.

In passing, it should be noted that these data were collected on the basis of a scientific sample. Thus, the figures quoted should not be viewed as necessarily representative of the U. S. utility scene. Nevertheless, I believe that they provide some insight into the current state of utility rates and regulations.
Tables 13 and 14 indicate the extent to which the companies have sought rate relief within the last year. Eighty-four of the companies had made at least one such application, with the First Federal Reserve District again accounting for more than 20 per cent of the total—and Kansas City and Richmond about 10 per cent each. The requests were distributed across the major types of utilities in about the same proportion as the number of respondents, with electric utilities representing nearly 42 per cent of the applicants. Turning to Table 14, it appears that of the 123 separate applications made by these companies, 46 per cent were granted in full, another 14 per cent were granted either in part or on an interim basis, while 40 per cent are still pending.

In the Middle West (perhaps for a variety of reasons), the regulatory climate appears to be rather unfavorable to prompt rate action. In Ohio, for example, delays of three years are not uncommon. Michigan currently bases its decisions on 1972 data, and intervenors add to the normal delay between application and granting which can be 9 months or more if the state government is involved. Illinois and Missouri must act within 11 months and generally avail themselves of the full time; Indiana's lag runs from 9 to 12 months. If lags are not too long, the rate adjustments are often too small. The Kansas City Bank reported this complaint of its respondents, many of whom had not had rate increases for many years. One utility in Kentucky (whose per share...

a A third gas utility has such relief on an emergency basis.

3. Automatic Cost Pass-Throughs. Since so much of the Northwest electric generating capacity is hydroelectric, utilities in Washington and Oregon generally do not have such clauses. Otherwise, as Table 15 indicates, the majority of respondents reported automatic rate adjustments for fuel costs and purchased electricity as well. In many cases, such clauses had applied to nonresidential customers for some years, and the procedure was extended to all customers recently.

In addition, three companies in the Atlanta District can pass on local taxes, as can some companies in the Minneapolis Bank survey. Nebraska permits operating and maintenance costs to be passed on as well, and Illinois allows the pass-through of carrying costs on cash advances for gas exploration and R&D in coal gasification.

While these clauses help somewhat in handling the earnings squeeze induced by escalating fuel costs, the schemes vary considerably in the speed with which a cost increase is reflected in a rate increase.

General comments were not specifically solicited. But several Districts reported a general company concern with inflation, with problems in raising long-term funds, and with delays and lags in the granting of licenses for both new and improved old facilities. These concerns are shared by many observers.

Utility Pricing and Consumer Welfare As is generally known, the historic pattern of utility pricing in the U.S. is to favor the large commercial or industrial users with lower rates than are charged residential or small commercial customers. Within the latter group, the typical declining block rates result in lower unit costs for those who consume large amounts of electricity than for those with more modest demands. Table 16 presents data on the distribution of sales of energy units for electricity and gas to various types of customers. Table 17 gives the percentage distribution of sales among major types of users.

These data show clearly that the small users—while consuming a relatively small amount of the energy produced—account for a large part of the revenues paid to utilities. This pattern is clear throughout the time period covered by the data. For example, in 1972, residential and domestic users took 32 per cent of all electricity consumed; in the same year, they accounted for 42 per cent of revenues received by electric utilities. For residential gas customers, this pattern is even more striking. Residential use stood at only 30 per cent of all consumption, but revenues from such customers amounted to nearly one-half of total revenues.
Moreover, the data on electrical energy consumption and revenues indicate that, when commercial customers are separated into large and small user categories, it is again the small user who makes the relatively large contribution to utility revenues. In 1972, small commercial and industrial electric consumers accounted for a larger share of revenues than they did of electrical use (29 per cent versus 23 per cent). The reverse is true for large commercial and industrial electric consumers. Their contribution to electric utility revenues was only 25 per cent while their consumption was 46 per cent.

Table 18 presents data on the rates charged to various types of customers. These data again point out that the small customers paid a higher price per unit of energy consumed over the entire time span. In fact, in 1972, the residential electric consumer paid over twice as much per kilowatt hour as the large

16 ECONOMIC REVIEW, JULY/AUGUST 1974

commercial customer. In the same year, residential gas consumers paid a rate over two and one half times as high as the industrial consumers.

To a considerable extent these rate relationships simply reflect the differences in average consumption levels among the groups, since in the case of larger users, fixed customer and demand charges are being spread over more units. Furthermore, there are clearly some physical efficiencies in delivering energy to large users. Producing and maintaining the large and complex distribution networks which characterize residential gas or electric lines is expensive. In addition, in the case of electrical energy distribution, energy can be saved by using high voltage lines to deliver electric service to large customers. Nevertheless, it is clear that the historic pattern of U. S. utility pricing results in a quantity discount scheme which heavily favors the large users. This pricing pattern in turn tends to encourage households to adopt consumption patterns which are highly energy
dependent and industry to develop in the direction of energy intensive production technologies.

The energy crisis which has been building in this country—and indeed in the world at large for the last several years and which culminated in the Arab oil embargo last fall and winter—has caused many observers to review the basic principles of energy pricing. Much traditional regulatory thinking assumes a natural monopolist who will reap even more lavish rewards from his declining long-run marginal cost curve (LRMC) unless rates are lowered. However, it now seems unlikely that economies of scale and technical improvements in the future will be sufficient to offset inflation and high imbedded debt costs. No one doubts any longer that energy is now both an increasing cost industry and an increasingly competitive one, when substitutions among energy sources are considered. Although some state officials regulating public utilities have called on utility management to trim costs rather than expect increases in rates, the presumption among most observers is that rates will have to rise. This will be necessary not only in order to attract funds for the necessary increases in capacity and environmental quality, but also in order to perform an allocative function as well.

Recently in discussions of rate making there has been a shift of emphasis from revenue and fair return to the structural and procedural aspects of rates and regulation. Proposals for improving the system's responsiveness to changes in costs include the use of projected rather than historical test years; the encouragement of research and development and long-term policy formulation; an extension of automatic adjustment clauses and interim relief policies to reduce regulatory lag, and the use of Federally-guaranteed bonds to raise capital without resorting to large rate increases.

One basic argument often advanced by environmentalists in support of a reform of utility pricing practices is that, if energy is indeed a scarce commodity that should be conserved, rewards should be given to the small user and penalties extracted from the large users. This proposed pricing scheme, the reverse of the present pricing system, is called the inverted block rate schedule. Yet, however attractive its distributional properties may appear, this scheme does not meet criteria of economic efficiency as well as do some other approaches.

Several authorities have begun to advocate replacing the present system of declining block rates with a structure which more nearly approximates marginal cost pricing since the price of energy should cover the incremental cost of providing it—if we are to avoid both an uneconomic degree of use and an unnecessary expansion of capacity. Such a structure would include peak load rate differentials for both time of day and season of the year, and fixed customer charges would be explicitly assessed. This scheme would have little impact on industrial users, and there would presumably be a tendency to redis-

Source: See Table 16.
tribute the costs of electric use toward the more affluent residential users, whose large consumption tends to contribute heavily to a system's peaks. This proposal is further modified by adding the stipulation that these costs should include provisions for damage to the environment. For instance, fees should be collected for the burning of high sulfur coal in an electric utility. The fees would be collected by a public agency and used to clean up the environment. While I realize that the correct measurement of all these costs is not a simple matter, there seems little doubt that many rate schedules could be made more reflective of incremental costs than they are at present.

Exactly which of these routes (or still some others) should be followed to reform utility practices is a matter of continuing debate. But, in the meantime, it is clear that we as a society must give careful consideration to the way in which we are to allocate our scarce energy resources. Moreover, we should all accept the fact that this growing scarcity will mean higher prices for energy relative to most other items on which consumers can spend their income. In the long-run, it is better to permit these increases in real costs to be passed on to final users—rather than pretend that we can—somehow—escape the burden. Only in this way will consumer welfare be truly served in the years ahead.
State Taxation of Fifth District Banks

Until recently, the powers of the states to tax banks have been narrowly restricted by Federal statutes. Most important among these laws was the famous Section 5219, U.S. Revised Statutes, 12 U.S.C. (hereafter: "Section 5219"), which limited the types of taxes that states could levy on national banks. The restrictions of Section 5219 date back to the 19th century, to the days when national banks had currency-issuing and fiscal agency functions and could legitimately be considered "instrumentalities of the Federal Government." The Federal Reserve System long ago took over these functions, thereby rendering Section 5219 obsolete. Recognizing the obsolescence of the law, Congress in 1969 moved to revise it by means of a "temporary amendment," which allowed states to apply most types of taxes to national banks. Moreover, a "permanent amendment," initially scheduled to become effective in 1972 but subsequently deferred until January 1, 1973, went further and completely rewrote Section 5219 to specify that national banks could henceforth be taxed in the same manner as state banks. This article, focusing on the Fifth District, discusses in turn the major types of taxes paid by banks under the old Section 5219, the changes in state tax treatment of banks following enactment of the "temporary" and "permanent" amendments, and the possibilities for further change now that the "permanent amendment" is in force.

Major Forms of Bank Taxation The original Section 5219, enacted as part of the National Banking Act of 1864, allowed states and their political subdivisions to levy real estate and shares (capital stock) taxes on the newly created national banks. As amended in the 1920's, Section 5219 permitted the states to substitute either an income tax or an excise tax "according to or measured by" net income for the shares tax, if they wished. No other form of taxation could be applied to national banks. Nothing in Federal law prevented other types of taxes from being applied exclusively to state-chartered banks. Such instances of discriminatory taxation, however, have been rare in recent years, at least in the Fifth District. As Chart 1 demonstrates, more than 80 percent of the taxes paid by all banks to state and local governments (with the exception of the District of Columbia) in 1969, the last year under "old" Section 5219, were of the types applicable to national banks. Most of the remaining taxes, such as the sales tax in South Carolina and the tax on bank deposits in North Carolina, were officially levied on state banks and paid "voluntarily" by national banks. The "voluntary" tax arrangement effectively skirted the restrictions of Section 5219. As might seem obvious, however, no major

---

1 Not only were these common types of taxes; but they had been specifically designated as permissible, if applied by a state to the Bank of the United States, by Chief Justice John Marshall in his famous decision in the McCulloch vs Maryland decision, 4 Wheat. 316 (1819). The legacy of that decision was undoubtedly a factor responsible for the restrictions of Section 5219 in the first place.

---

1 The District of Columbia was never subject to Section 5219. Instead, Congress imposed a gross receipts tax of 7 percent on banks operating in the District. The District sales tax has also applied to purchases made by national banks.

Federal Reserve Bank of St. Louis
amounts of revenue were collected from banks in this manner.

Of the three major modes of bank taxation, one, the tax on real property, is almost exclusively within the province of the local city, town, or county governments. It exists everywhere, but presents no novel features when applied to banks, so little more need be said about it here. State governments, for their part, were left to choose between the shares tax and the income tax.

Shares Taxes In thirteen states, including Virginia and West Virginia, banks pay a shares tax rather than an income tax. Originally, the shares tax derived from the general property tax; and it still retains much of the character of a property tax in West Virginia, where the tax is paid on the basis of "true and actual value" of bank shares, minus a deduction for real property taxes. The assessments are made by the individual counties, which also set the rates. Virginia’s tax, on the other hand, is a flat tax on bank capital, surplus, and undivided profits, minus a deduction for the assessed value of real property. The rate is 10 mills (1¢) per dollar value. The state collects the tax; but half the revenues are shared with the cities and towns, which can, additionally, levy their own shares tax if they wish, at rates up to 8 mills per dollar value. In such cases the local tax is credited against the state tax. Both states levy the tax officially on the shareholder; but it is, in practice, collected and paid by the bank.

For a long time the shares tax was the most popular tax levied on banks, even after the 1920’s amendments to Section 5219 permitted income taxes. The shares tax fit well into the general tax structure of most states, was relatively high-yielding, and did not rise and fall with bank income—a virtue, perhaps, from the point of view of the states seeking revenue in the unstable banking era that lasted until 1933. The tax does have notable disadvantages. In some states the vagaries of local assessment procedures probably resulted in uneven and discriminatory levies. The tax, additionally, falls on capital and thus provides some incentive to minimize the amount of capital held. Most bankers have come to view the income tax as a fairer tax, and most states, in a period of high and rising bank income, have seen it as a more lucrative source of revenue. Accordingly, thirty-seven states have switched to the income tax since 1926, and none has switched back. For all that, the shares tax does not seem to be distinctly inferior to the income tax, which has some disadvantages of its own.

Income Taxes States that first switched to the income tax in the 1920’s did so by simply making banks subject to existing state corporation income taxes. As such, they found an income tax on banks to be a disappointing source of revenue, because Federal debt statutes prohibit state taxation, under a direct income tax, of that part of income consisting of interest from U. S. Government securities. For the purpose of taxing most types of businesses, this provision hardly matters, but banks are a special case. Because of their large holdings of various U. S. Government securities, a significant portion of their income is exempt from taxation under state income tax laws. Furthermore, states had no way to compensate for this shortfall, because Section 5219 and constitutional law prohibited either raising tax rates on national banks alone or introducing other taxes to compensate. Another avenue was open, however. By designating the tax a “franchise” or “excise” tax, “measured by or according to” net income, the states could, in fact, bring interest income from Federal securities under the income tax. This redefinition involved no essential change in the nature of the tax, other than one of wording. In a 1926 amendment to Section 5219, Congress sanctioned the application of this “excise” income tax to national banks. More recently, the “excise” income tax has become widely applicable. Nearly all of the state income taxes paid by banks, including the bank income taxes of Maryland, North Carolina (until this year), and South Carolina have been of this variety. The rates in these states are 7 percent, 6 percent, and 4½ percent, respectively.\(^3\)

The “excise” income tax has been popular both with the state governments and, generally but not universally, with bankers. The former view it as a lucrative source of revenue, especially when rates are as high as 6 percent; the latter see it as a fair tax, covering a broad but easily definable tax base that varies roughly with ability-to-pay, i.e., with net income. Nevertheless, the “excise” income tax does have some deficiencies as a form of taxation. First, the incidence of the tax, as for all corporate income taxes, is not known for sure; it could be, for example, that the tax falls on capital as much as does the shares tax. Secondly, as is better known, the “excise” income tax has some portfolio-distorting effects. Because the tax falls on U. S. Government securities

---

\(^3\) These are, of course, nominal rates. The effective rates of tax could only be determined by examining in detail the various specific definitions of the tax base, allowable deductions, etc. No attempt to do so will be made here. For a description of the major feature of the tax in each state, see Commerce Clearing House, State Tax Guide, 1973. Some indication of the effective rates of tax may be found in the interstate comparison of tax burdens, discussed later in the article.
but generally not on in-state municipal securities, the effective yield of the former to the banks is reduced relative to that of the latter. Banks end up buying more municipals and fewer Governments than otherwise, and perhaps, their total after-tax yields are lower than they might be if another type of tax were in effect. Of course, the magnitude of this distortion may be small if it exists at all and is in any case dwarfed by a far larger distortion caused by similar rules involved in determining the Federal income tax base. Future efforts at tax reform in the "excise" income states may, however, center around this distortion factor, especially since other tax alternatives, under the "new" Section 5219, are now available to the states.

A Comparison of Interstate Tax "Burdens" Attempts to measure the extent of corporate tax burdens are always hampered by a host of formidable problems. For one thing, the incidence of different taxes is often difficult to detect and still more often difficult to measure. Moreover, even if the incidence problem is ignored, measures of tax burden, which are ratios comparing total taxes paid to some indicator meant to represent taxable capacity, are necessarily arbitrary, since no one yet has devised a reliable measure of taxable capacity, or, for that matter, a precise definition of what taxable capacity really means.

Subject to these caveats, Table I compares the amounts of taxes paid by banks in each Fifth District state and the District of Columbia. Although four different measures of taxpaying capacity are used, it appears that the comparative results are virtually the same in each case. The results, not surprisingly, mirror the effects of varying tax rates on income or share taxes, although all taxes are included. The apparent implication is that high tax rates, rather than the type of taxes imposed, are the important factors making for relatively higher tax burdens.

The figures in Table I are for 1969, the last year for which such data are available. As will be shown in the following section, however, the effects of changes in tax rules since 1969 on the Table I figures are not difficult to estimate.

Changes Since 1969 The "temporary amendment" to Section 5219 significantly liberalized the rules. After 1969, states were restricted only from taxing national banks on the basis of intangible personal property and from levying certain types of taxes on out-of-state banks. The lingering ban on intangible property taxation was removed when the "permanent amendment" came into effect in 1973. These new regulations led the legislatures in the Fifth District states to reassess their tax treatment of banks. Varying degrees of change resulted.

In most cases the changes were relatively minor. Sales and use taxes on purchases of equipment and other material items were made applicable to both national and state banks in each state or were made compulsory where they had been "voluntary." National banks became subject to documentary taxes, license taxes, motor vehicle registration taxes, and any other such general category from which Section 5219 had exempted them. sulting differences in bank revenues are not available; but a fair guess would be in the range of 5 to 10 percent, depending on the types of taxes and the rates of tax, which vary among the states.

An additional more substantive change took place in West Virginia, where banks became subject in 1971 to the state’s “business and occupation tax,” a tax on gross receipts of 1.15 percent. It may be recalled from Table I that bank tax burdens in West Virginia were the lowest of all the Fifth District states in 1969. The gross receipts tax is likely to redress the balance.

The most drastic changes in the Fifth District took place in North Carolina, during the 1974 legislative session. The excise (income) tax was repealed, along with a series of in lieu provisions that had exempted banks from certain other state taxes paid by North Carolina corporations. Under the new tax law the banks instead became subject to the latter categories of taxes, which include (1) a corporate income tax, with income from U. S. Government securities exempted; (2) a corporate franchise tax; (3) taxes on tangible personal property, as levied by local governments; and (4) an “intangibles” tax, to be paid on the basis of total vault cash as of December 31 of each year. As it was estimated that the revenues from this new batch of taxes would not completely compensate for the revenue loss resulting from repeal of the existing law, a fifth tax was added. This additional levy, a state “privilege license tax,” consists of a lump sum payment of $30 for each $1 million, or fractional part, of total assets. For tax purposes, “total assets” for any year consist of the average of total assets at the end of each quarter. As a partial offset to this state tax, local governments are henceforth prohibited from levying such “privilege” taxes of their own, as many have done since 1969.

The chief purpose of the North Carolina tax changes appears to be uniformity in the tax structure. Taxing banks in the same manner as other corporations, to the maximum extent possible, was seen as a goal in itself—a goal that was clearly impossible under the old Section 5219. The new law is not meant either to increase or decrease bank tax burdens. It is, of course, too early to tell whether this effect has been achieved. In all probability, however, deviations in either direction will be of no great magnitude.

Under the Permanent Amendment: The Scope for Further Change There has not been any tendency among other Fifth District states to emulate North Carolina by completely revising the tax laws affecting banks. Nor do any such changes appear to be in the offing. All changes, great and small, that have taken place do, however, follow that same general pattern: greater uniformity of tax treatment of banks and other corporations. Few of the new taxes affecting banks have applied to banks, or to financial institutions, alone, but rather to businesses generally. It is obvious that absolute uniformity cannot be achieved—not, at any rate, without serious inequities. A major portion of business taxes in nearly all states derives from the corporation income tax, under which banks generally pay less than other corporations under an ordinary income tax, owing to the mandatory exemption of interest from U. S. Government securities. Whatever the desire for tax uniformity, state governments will always find it in their interest to make up the inherent revenue shortfall, either by applying an “excise” income tax, by taxing banks on the basis of shares or gross receipts instead of income, by a lump sum or “privilege” tax (as in North Carolina), or by some combination of these alternatives.

On the other hand, there has been no tendency to subject banks to heavy taxation in light of removal of the Section 5219 restriction, or to levy taxes which, even if applied to all businesses, might fall disproportionately on banks. One such tax would be a general tax on “intangible” property. Most bank assets are intangible property. During the hearings preceding the amendments of 1969 and 1973, some observers expressed fears that states might impose “intangible” property taxes that would apply to loans, vault cash, and perhaps even (for member banks) required reserves held on deposit at Federal Reserve Banks. In a 1971 study prepared for Congress, the Board of Governors cited the dangers of intangible taxes: the incentive to evade would be great; assets subject to tax would be transferred to holding companies, or to subsidiaries, or out of state; banks would switch their assets from taxable to nontaxable form; loan customers would have incentive to apply out of state, or to avoid the banking system altogether; general inefficiency and waste would result. As we have seen, a ban on intangibles taxation was inserted into the temporary amendment, but not into the permanent amendment. It would seem, however, that the imposition of such taxes will remain unlikely. Intangibles taxation has become unpopular among the states. The general tendency during the last few decades has been to repeal such taxes, not to enact them. Where this form of taxation still exists, as in North Carolina (noted above), it is in an extremely restricted form and unlikely to have any dire effects.
State and local revenue needs are not as pressing at the present time as they were a few years ago, so additional taxes on Fifth District banks do not seem likely in the immediate future. Any future tax initiatives—barring an overhaul similar to North Carolina’s—would, in all probability, take the form of higher rates on existing taxes, rather than new forms of taxation. It is even less likely that a disproportionate share of any increased taxation would fall on banks, even with the shield of Section 5219 removed.

Sources of Bank Taxation: The Question of Out-of-State Banks States have not ordinarily levied taxes on banks domiciled in other states, but the permanent amendment, in theory, gives them the power to do so. Taxation of out-of-state banks, however, might prove to be a complicated matter, owing to the difficulties likely to arise from any attempt to apportion the tax base and the limits to taxation of interstate commerce imposed by constitutional law. For example, if a bank in State A made a loan to a customer in State B, it is not easy to see how State B could subject the bank to, say, income taxes on the interest income from that loan, without imposing unfair, and possibly unconstitutional, double taxation (if the bank already pays tax to State A). The inherent possibilities for ambiguous interpretations of tax laws and arbitrary interstate taxation of banks, with the distortion of capital mobility that would inevitably result, led the Board of Governors to recommend in the above-mentioned report that limitations on interstate taxation of banks be continued under the permanent amendment, at least until uniform, equitable, national standards for such taxation could be developed. The recommendation was not adopted, but Public Law 93-100, enacted in August of 1973, imposed a new ban, lasting until January 1, 1976. Meanwhile, the Advisory Commission on Intergovernmental Relations was directed to prepare a study of the whole question, with a completion date of December 31, 1974. Presumably Congress will again take up the matter in 1975. A future relaxation of the current prohibition, which is not altogether inconceivable, would undoubtedly lead to a corresponding change in state tax policies.

Conclusion It would seem that the tax changes induced by the alterations in Section 5219 have not been far-reaching, at least as far as revenues and tax burdens are concerned, and that further substantial changes are unlikely in the near future. The implication is that the “old” Section 5219 was not so restrictive, after all. Even so, there is no doubt that the changes in the law were desirable. First, the amendments to Section 5219 resulted in the removal of some completely unnecessary prohibitions (the sales tax being the most obvious example), which is sufficient justification. Second, as the example of North Carolina illustrates, the changes leave individual states free to handle the issues of bank taxation in whatever manner seems most appropriate. The changes have not, as yet at least, resulted in any adverse effects.

THE CHANGING FACE OF FIFTH DISTRICT AGRICULTURE This study is an analysis of the transition that has taken place in Fifth District agriculture since World War II. It reviews the changes of the past quarter century, examines the major factors that have produced the transformation, and, finally, analyzes some of the implications for the future. Implications for farm lenders comprise one of the major sections of the study. 148 pages. 1973.

FIFTH DISTRICT FIGURES A compilation of economic statistics, including data on resources, income, employment, agriculture, mining, business and trade, utilities, and finance. Figures on Fifth District States and Standard Metropolitan Statistical Areas are compared with data for the United States. 112 pages. 1974.

INSTRUMENTS OF THE MONEY MARKET This booklet, in addition to describing a number of short-term, highly liquid instruments, also pictures in general terms the institutional arrangements of the markets in which these instruments are traded. The booklet begins with a general review of the money market, followed by a fairly detailed description of 10 money market instruments. Emphasis throughout is on the interrelatedness of the various sectors comprising the money market. 100 pages. 1974.
