A Survey Questionnaire

In this appendix, we provide details on survey instrument about year ahead labor market outcomes in the Copenhagen Life Panel. To set the stage, we start by asking questions about work status in the past year. In the survey fielded in January 2021, the first question is about labor market status one year earlier, in January 2020. Respondents were asked to classify themselves as one of: employed; self-employed; looking for work; temporarily out of labor force; and permanently out of labor force.

Respondents then report their current work status. They again can choose from among the same five options. If they report there is a change between the past and current status, we further ask about the dynamics. Then they move to the module with expectations questions if they are currently employed. The full questionnaire is as follows:

First, we are interested in your working status in Jan 2020 (last year).

Throughout this survey, we are going to ask you about working for pay. We have in mind work, including work as self-employed, for which you receive regular pay and work at least 10 hours per week.

[Part 2-1: Labor income, Past]

Q_2_1. Think about Jan 2020 (last year).

Were you working for pay?

Variable name: Q_2_1

Variable value: 1 Yes 2 No

[If Q_2_1=Yes] Q_2_1_2. Think about Jan 2020 (last year).

Were you self-employed?

Variable name: Q_2_1_2

Variable value: 1 Yes 2 No

[If Q_2_1=No] Q_2_1_3. Did you look for work in Jan 2020?

Variable name: Q_2_1_3

Variable value: 1 Yes 2 No

[If Q_2_1_3=No] Q_2_1_4. Please pick the most appropriate description of your employment status in Jan 2020 (last year).

Variable name: Q_2_1_4

Variable value: 1 Temporarily out of work, 2 Permanently out of work

[Note: clarification Johan]

[If J_past= Temporarily Out/Looking for work] Q_2_2. Did you have any earned income during 2020?

Variable name: Q_2_2

Variable value: 1 Yes 2 No

[If Q_2_1=Yes or Q_2_2=Yes] Q_2_3. What was your earned income during 2020?

Please report the most accurate amount you think.

Variable name: Q_2_3

Variable value: [0-]

[Part 2-2: Labor income, Dynamics]

[If J_past=E WFP] Q_2_4. From Jan 2020 till now, are you still working for pay with the same employer you had in Jan 2020?

Variable name: Q_2_4

Variable value: 1 Yes 2 No

[if Q_2_4=No] Q_2_4_2. When did you stop working with this employer you had in Jan 2020?

Variable name: Q_2_4_2

Variable value: From Jan-1-2020 – to Jan-2021

[if Q_2_4=No] Q_2_4_3. For what reason, did you stop working with this employer you had in Jan 2020?

Variable name: Q_2_4_2

Variable value: 1.Laid-off, 2 Quit, 3 Other

[if Q_2_4=No] Q_2_4_4. After you stopped working for this employer you had in Jan 2020, did you find other work for pay within a month?

Variable name: Q_2_4_4

Variable value: 1 Yes 2 No

[if Q_2_4_4=No] Q_2_4_5. How many months were you out of work after you stopped working for the employer you had in Jan 2020.

Variable name: Q_2_4_5

Variable value: [1-12, I did not work for pay after that]

[Part 2-2: Labor income, Now]

We now ask about your current employment status.

[if Q_2_4!=Yes, Q_2_5!=Yes] Q_2_7. Are you currently working for pay?

Variable name: Q_2_7

Variable value: 1 Yes 2 No

[If Q_2_7=Yes] Q_2_7_2. Are you currently self-employed?

Variable name: Q_2_7_2

Variable value: 1 Yes 2 No

[If Q_2_7=No] Q_2_7_3. Are you currently looking for work for pay?

Variable name: Q_2_7_3

Variable value: 1 Yes 2 No

[If Q_2_7_3=No] Q_2_7_4. Please pick the most appropriate description of your current employment status

Variable name: Q_2_7_4

Variable value: 1 Temporarily out of work, 2 Permanently out of work

[Part 2-3: Labor income, Future]

[if J_now=E WFP] Q_2_8. Please think about your possible relationship with your current employer in 2021. Assign the probability in each possible case. The sum of the probability should be 100.

1. Staying with the current employer during 2021
2. Laid-off from current employer at some point during 2021
3. Quit from the current employer at some point during 2021
4. Separation for other reason [checkbox activated]

Variable name: Q_2_8_1, Q_2_8_2, Q_2_8_3, Q_2_8_4

Variable value: [0-100]

[Stay branch] [if Q_2_8_1>0] Q_2_9. We are interested in your earned income in 2021 if you stay with the current employer throughout the calendar year 2021.

Variable name: Q_2_9_1, Q_2_9_2, Bins and balls

[if Q_2_8_1>0] Q_2_10. Now, please think about your earned income in 2025 if you stay with the current employer throughout the calendar year 2021.

Please think about all possibilities regardless of whether you stay with the same employer after 2021.

Variable name: Q_2_10_1, Q_2_10_2, Bins and balls

[Laid-off branch] [if Q_2_8_2>0] Q_2_11. Suppose you were to be laid off from the current employer during 2021. What is the probability that you would start working for pay again after your current work terminates?

Variable name: Q_2_11_1 (within 1 month), Q_2_11_2 (within 3 months), Q_2_11_3 (within 1 year), Q_2_11_4 (within 2 years) **[Custom 58]**

[if Q_2_11_4>0] Q_2_12. Suppose you were to be laid off from the current employer during 2021. After then you start to work for pay at some point in 2 years.

Think about the possible earned income from the first 12 months of this new work for pay.

Variable name: Q_2_12_1, Q_2_12_2, Bins and balls

[if Q_2_11_4>0] Q_2_13. Suppose you were to be laid off from the current employer during 2021. After then you start to work for pay at some point in 2 years.

Think about the possible earned income in 2025.

Think about all the possibilities between reemployment and 2025.

Variable name: Q_2_13_1, Q_2_13_2, Bins and balls

[Quit branch] [if Q_2_8_3>0] Q_2_14. Suppose you were to quit from the current employer during 2021. What is the probability that you would start working for pay again after you quit?

Variable name: Q_2_14_1 (within 1 month), Q_2_14_2 (within 3 month), Q_2_14_3 (within 1 year), Q_2_14_4 (within 2 years)

[if Q_2_14_4>0] Q_2_15. Suppose you quit from the current employer during 2021. After then you start to work for pay at some point in 2 years.

Think about the possible earned income from the first 12 months of this new work for pay.

Variable name: Q_2_15_1, Q_2_15_2, Bins and balls

[if Q_2_14_4>0] Q_2_16. Suppose you quit from the current employer during 2021. After then you start to work for pay at some point in 2 years.

Think about the possible earned income in 2025.

Think about all the possibilities between reemployment and 2025.

Variable name: Q_2_16_1, Q_2_16_2, Bins and balls

[Other branch] [if Q_2_8_4>15] Q_2_17. Suppose you were to be separated because of other reasons you are thinking of (not laid-off or quit).

What is the probability that you would start working for pay again after your current work?

Variable name: Q_2_17_1 (within 1 month), Q_2_17_2 (within 3 months), Q_2_17_3 (within 1 year), Q_2_17_4 (within 2 years)

[if Q_2_17_4>0] Q_2_18. We are interested in your earned income in the first-year and 2025 earned income after you are separated for other reasons and then reemployed.

Suppose you were to be separated for other reasons from the current employer during 2021. After then you start to work for pay at some point in 2 years.

Think about the possible earned income from the first 12 months of this new work for pay.

Please report your lowest and highest possible amount.

Variable name: Q_2_18_1, Q_2_18_2, Bins and balls

[if Q_2_17_4>0] Q_2_19. Suppose you were to be separated for other reason from the current employer during 2021. After then you start to work for pay at some point in 2 years.

Think about your earned income in 2025. Think about all the possibilities between reemployment and 2025.

Please report your lowest and highest possible amount.

Variable name: Q_2_19_1, Q_2_19_2, Bins and balls

B Comparison to Administrative Data

Table B.1 compares the demographics of the survey sample with that of the comparable registry population. The first column is for all survey participants and the second column is for employed samples. The third column is for everyone in the registry and the fourth column is for workers with annual earnings greater than 24,000 DKK. We note that the share of females is similar in the survey and the registry. Survey participants are, on average, older, more educated, and have higher earnings than the registry population.

Table B.1: Survey sample demographics

Working status	Survey		Registry	
	All	Employed	All	Employed
N	14,875	10,945	3,429,071	2,700,069
Female	0.48	0.48	0.5	0.48
Age				
Mean	48.00	47.44	42.50	42.56
S.D.	12.54	11.87	13.26	12.77
Distributions				
20-29	0.11	0.10	0.22	0.21
30-39	0.15	0.16	0.20	0.21
40-49	0.22	0.24	0.22	0.24
50-59	0.31	0.33	0.23	0.24
60-65	0.21	0.17	0.12	0.10
Education				
Above college	0.49	0.53	0.34	0.39
Annual Earnings (unit: DKK)				
Mean	421,278	495,783	327,525	418,624
S.D.	382,719	289,681	430,482	442,410

Note: The table compares average demographic characteristics of different subsamples of the Danish population observed in the administrative data in 2020. The column ‘Survey, All’ includes gross sample of survey participants. The column ‘Survey, Employed’ includes the subset of survey participants who were employed at the time of the survey (January 2021). The column ‘Registry, All’ includes all individuals in the Danish population belonging to the cohorts from which the sample is drawn. Survey participants are excluded from this sample. The column ‘Registry, Employed’ includes the subset of the previous column with earned income of at least 24,000 DKK in 2020. In Jan-2021, the exchange rate for 1 US Dollar was approximately 7 Danish Krone (DKK).

In the analysis we scale all statistics by the relative population weights. To construct population weights, we use the Danish population observed in 2020 in the administrative data. We estimate a probit regression with a survey participation dummy as the dependent variable and age, log earnings, education, and gender as explanatory variables. All these

characteristics are available in the administrative data. Table B.2 shows the marginal effect on survey participation using probit regression. Our survey respondents are around 0.37% of the Danish population. We find that the selection into the survey is related to various demographics. For instance, as age increases by one unit, the probability of participation increases by 0.012%.

Table B.2: Marginal effect on participation

	Mean of Pr(participation):0.37%		
	$\frac{dy}{dx} \times 100$	z-statistics	p-value
age	0.012	49.47	<0.001
female	-0.028	-4.45	<0.001
log earnings	0.015	19.38	<0.001
above university	0.228	29.9	<0.001
N: 2,711,011			
Log-likelihood: -92,294			

Note: The table presents marginal effects from probit regressions where the dependent variable is a dummy variable for survey participation.

To obtain population weights for the survey, we use the inverse of the predicted probability of participating in the survey. Then we apply these population weights to the analysis and figures in the main text.

C Supplementary Results

C.1 Distributions of Job Transition Probability and Time Out of Labor Force

In this section, we show the distribution of job transition probability and time out of the labor force after the job separation in Fig 4.

Fig C.1 (a) displays the distribution of the probability of stay, laid-off, and quit, respectively. We observe that the probability of quitting is slightly more heterogeneous than the probability of being laid-off, although qualitatively they are quite similar. We also find the probability of stay has the most heterogeneous distribution among the three branches. Fig C.1 (b) illustrates the distribution of time out of the labor force after quitting and being laid off, respectively. Notably, the time out after quitting exhibits peaked distribution where the peak is close to 0. This means most workers expect very short periods of time out of work. In contrast, the time out after being laid off is more similar to a uniform distribution with much less peakedness.

Note: Panel (a) shows the distribution of the probability of each branch. Panel (b) shows the distribution of time out labor force after quitting and being laid off respectively.

Figure C.1: Distribution of Fig 4.

C.2 Standard Measures of Higher Order Moments

Figure C.2 shows the cross sectional distribution of moments of the subjective distribution calculated using standard measures (standard deviations, skewness, and kurtosis). This figure corresponds to Figure 4 in the paper. The distribution of moments using standard measures are quite similar to the pattern in Figure 4 in the paper which is based on robust measures. Workers tend to have high second moments after being laid-off and quitting, while it is much lower in the stay branch. The skewness is also consistent with the Kelley skewness in Figure 4. Across the branches, it is centered around 0. Lastly, the kurtosis measure which we normalized by 3 (normal distribution) is also consistent with Crow-Siddiqui kurtosis, which is less peaked compared to the normal distribution.

C.3 Job Transitions Based on 2019 Data

Figure C.3 replicate Figure 4 in the main text using data from the 2019 registry. Figure C.3(a) shows the result for the stay probability against age. The pattern is very similar to the pattern presented in Figure 4(a) the main text. Figure C.3(b) replicates Figure 4(b) of the main text but now based on 2018-19 data. We find that the time out work pattern across the life cycle is very consistent.

C.4 Last Year's Earnings

In this section, we compare the subjects' reported earnings for 2020 to actual earnings in 2020 as recorded in the income-tax registry. Figure C.4 shows a binned scatter plot of average earnings reported in the survey (Y-axis) by bins of earnings recorded in the administrative data (X-axis), which is third-party reported by employers directly to the

Note: Standard moments of the answers to the questions in the conditional survey instrument. Survey results are weighted using population weights.

Figure C.2: Overview of branch-by-branch survey responses: using standard moments

Danish Tax Agency. We find that earnings reported in the survey is very similar to earnings recorded in the administrative data. This suggests that respondents remember their earnings during 2020 well at the point when we surveyed them in January 2021.

We further investigate whether observable characteristics correlated with the deviation between self-reported and registry earnings in 2020. We first construct the log gap between registry earnings and self-reported earnings: $\log(Y_{2020}^{\text{registry}}) - \log(Y_{2020}^{\text{survey}})$. The mean of this log gap is 0.048 and the standard deviation is 0.26. Table C.1 shows the regression results. In column (1), we include 5-year age bins, with the age 41-45 group as the baseline. Except for the youngest and oldest groups, the coefficients are not significant at the 5% level. Gender and education are also not significant at the 5% level. In column (2), we control for age as a continuous variable and find significant correlations at the 1% level, which means that older workers are relatively over-reporting their current earnings in the survey. When we control for age and the age-squared term in column (3), the coefficients are not individually significant at the 5% level. For all the regressions the R^2 is 0.005, i.e., the observable characteristics explain very little of the deviation. These

Note: The figure shows how two components from the survey (solid line) and the administrative data (dashed line) compare over the life-cycle. Panel (a): In the survey, we directly ask about the probability of staying with the same employer for the next 12 months. In the registry, we compute the proportion of workers who stayed from Dec 2018 to Dec 2019 with the same employer. Panel (b): We calculate the expected time out of work after a separation in the survey. In the administrative data we consider job separations that took place during 2018 and follow time spent until reemployment occurs, possibly extending into 2019. In the registry, 1) we exclude the workers going back to the same employer (possibly seasonal work) and 2) we consider the first separation and do not take into account further separations.

Figure C.3: Job separations and time out of work in the survey and in the administrative data for 2019

results show that it is difficult to find systematic under/overreporting in self-reported earnings across the included observable demographics.

C.5 Comparison with 2019 Registry

Figure C.5(b) replicates Figure 5(b) in the paper using administrative data from 2019. The figure shows survey and registry results side by side, and it is very similar to Figure 5 in the main text.

C.6 Registry Earnings Risk using Survey Respondents

Figure C.6 replicates Figures 5(b) in the paper using administrative data for 2020 only for survey respondents. While noisy because it includes fewer observations it compares well to Figure 5(b).

C.7 Standard Moments of h_S^X and h_A^X

Figure C.7 reproduces Figure 7(b)-(d) in the paper using standard deviation, skewness, and kurtosis. Also here we find that the moments are well aligned across the life cycle.

Table C.1: Difference between registry and self-reported survey earnings

Dependent variable:	$\log(Y_{2020}^r) - \log(Y_{2020}^s)$		
	(1)	(2)	(3)
Age group 20-25	0.046** (0.023)		
Age group 26-30	0.024 (0.016)		
Age group 31-35	0.020* (0.012)		
Age group 36-40	0.017 (0.012)		
Age group 46-50	0.008 (0.010)		
Age group 51-55	-0.010 (0.009)		
Age group 56-60	-0.012 (0.010)		
Age group 61-65	-0.026*** (0.010)		
Age		-0.002*** (0.000)	-0.001365 (0.002153)
Age-squared			-0.000002 (0.000023)
Female	0.007 (0.005)	0.007 (0.005)	0.007437 (0.005282)
University or above	0.008 (0.005)	0.008 (0.005)	0.007668 (0.005456)
Constant	0.035*** (0.011)	0.106*** (0.015)	0.103** (0.0483)
Observation	10,356	10,356	10,356
R ²	0.005	0.005	0.005
F-statistics	5.150	16.48	12.36

Note: Robust standard error in parenthesis. */**/** represent significance level 10/5/1%. Controls include age, gender, tenure, education, and log earnings in 2020.

Note: Binned scatter-plot comparing earnings observed in the administrative data and self-reported earnings in 2020.

Figure C.4: Self-reported and registry earnings: last year (2020)

C.8 Standard Moments of Subjective Earnings Risks

Figure C.8 reproduces Figure 10(b)-(d) in the paper using standard deviation, skewness, and kurtosis rather than the interdecile range, Kelley’s measure of skewness, and the Crow-Siddiqui measure of excess kurtosis. Figure C.8(a) and (b) are quite similar to Figure 10(b) and (c) in the paper. Figure C.8(c) shows a slightly different pattern than Figure 10(d) in the paper, as older workers exhibit less kurtosis according to the standard measure than according to the Crow Siddiqui measure of kurtosis.

D Method for Simulating Holistic Earnings Risks

This section explains how we simulate the subjective holistic distribution of earnings growth, g_i . The purpose is to construct g_i such that it matches the timing of the administrative data, i.e., the calendar year. To achieve this, we set up a simulation protocol, where we weight together, for each respondent, all the components entering each of the branches for individual i as described in the below equation.

$$\begin{aligned} \hat{g}_{i,s} = & (1 - \mathbb{1}[Q_{i,s} = 1] - \mathbb{1}[L_{i,s} = 1]) \hat{f}_{i,s}^S \\ & + \mathbb{1}[Q_{i,s} = 1] \left(\hat{n}_{i,s}^{Q,S} \hat{f}_{i,s}^S + (1 - \hat{n}_{i,s}^{Q,S} - \hat{n}_{i,s}^Q) \hat{f}_{i,s}^Q \right) \\ & + \mathbb{1}[L_{i,s} = 1] \left(\hat{n}_{i,s}^{L,S} \hat{f}_{i,s}^S + (1 - \hat{n}_{i,s}^{L,S} - \hat{n}_{i,s}^L) \hat{f}_{i,s}^L \right) \end{aligned}$$

where i, s indicates simulation number s for individual i . $\mathbb{1}[Q_{i,s} = 1]$ is a dummy

Note: Panel (a) plots log density for the pooled distribution of expected holistic earnings growth rates from the survey, h_S^X , where X indicates partitions by age groups. (b) plots the distribution of annual earnings growth from 2018 to 2019 as observed in the administrative data for the full population, h_A^X . For constructing the distribution of earnings growth in the administrative data we dropped observations where the level of annual earnings is less than 24,000 DKK in 2018. Survey results are weighted using population weights.

Figure C.5: Pooled earnings risk and registry earnings risk (data from 2019)

indicator for quitting for individual i in simulation s , $\mathbb{1}[L_{i,s} = 1]$ is a dummy indicator for being laid off. $\hat{n}_{i,s}^{Q,S}$ is time in the original job before quitting and $\hat{n}_{i,s}^Q$ is time spent out of work following the quit. Similarly, $\hat{n}_{i,s}^{L,S}$ is time in the original job before lay-off and $\hat{n}_{i,s}^L$ is time spent out of work following the lay-off. $\hat{f}_{i,s}^S$, $\hat{f}_{i,s}^Q$, and $\hat{f}_{i,s}^L$ are draws from the probability distribution over earnings growth in the stay, quit and lay-off branches respectively. Thus, the first term flags whether in simulation s , the individual stays in the current job and calculates the expected earnings in that job 12 months ahead when staying. The second term flags whether simulation s leaves i to quit and if that is the case, then calculates earnings during the next 12 months. This is composed of three parts: first, earnings in the original job until the separation followed by a period without earnings until a new job is found, and then earnings in the new job for the remainder of the year. The third term makes the corresponding calculation for a lay-off. Each simulation s produces a value for $\hat{g}_{i,s}$. By simulating many times for each respondent, we get a complete empirical probability distribution over the 12-months ahead of subjective holistic earnings growth. We now explain the details of the simulation. It proceeds in four steps:

1. Simulating job transitions, $\mathbb{1}[Q_i = 1]$, $\mathbb{1}[L_i = 1]$: We simulate 20,000 job transition events for each individual based on the stated job transition probabilities (stay, laid off, and quit) in 2021.
2. Simulating time spent out of work: For the job transition events, quit and lay-off

Note: The figure plots the distribution (log density) of annual earnings growth for 2020 as observed in the administrative data for the survey participants.

Figure C.6: Registry earnings risk (survey respondents only)

from step 1, we simulate time spent out of work. This happens in two steps:

1. We first simulate the timing (month) of separation during 2021. We assume that the separation happens on day 1 of the month. To simulate the month of separation, we first recover the monthly density of the job transition. Let P_l and P_q be the reported probabilities of being laid off and quitting at some point in 2021. Based on P_l and P_q we can recover the monthly probabilities p_l and p_q using two simultaneous equations. We let a geometric series describe the probability of separating from the initial job in a given month.

$$P_l = \underbrace{p_l}_{\text{Jan}} + \underbrace{(1 - p_l)p_l}_{\text{Feb}} + \underbrace{(1 - p_l)^2 p_l}_{\text{Mar}} + \dots + \underbrace{(1 - p_l)^{11} p_l}_{\text{Dec}} \quad (1)$$

$$P_q = \underbrace{p_q}_{\text{Jan}} + \underbrace{(1 - p_q)p_q}_{\text{Feb}} + \underbrace{(1 - p_q)^2 p_q}_{\text{Mar}} + \dots + \underbrace{(1 - p_q)^{11} p_q}_{\text{Dec}} \quad (2)$$

We then construct a distribution of job transitions across months and based on this distribution we simulate a month in which the job separation event occur, i.e., $\hat{n}_{i,s}^{Q,S}$ and $\hat{n}_{i,s}^{L,S}$.

2. Then we simulate the timing of reemployment. We do this using the stated probabilities of being reemployed after 1, 3, and 12 months after the job separation. To do this, we linearly interpolate the probability of reemployment over months and then construct the monthly reemployment distribution. Using this monthly distribution of reemployment, we simulate the duration of the intermediate job search period after the separation. We assume that the

Note: The figure shows the average value of the 1st to 4th moments of the pooled earnings distribution by age in the survey, h_S^X , and in the administrative data, h_A^X . “o” and “x” represent the empirical mean across 5-years age bins for the survey and the administrative data for 2020, respectively. The lines are local linear polynomials, calculated using a bandwidth of 4 years. Survey results are weighted using population weights. The figure corresponds to Figure 6 in the paper, but uses standard measures for calculating variance, skewness and kurtosis as opposed to Figure 6, which is based on robust quantile based measures.

Figure C.7: Life cycle patterns in pooled risks moments

reemployment happens at the beginning of the month.

3. Simulating conditional earnings distributions, $\hat{f}_i^S, \hat{f}_i^Q, \hat{f}_i^L$

For each given simulated event we draw an earnings realization from the relevant conditional earnings distribution $\hat{f}_i^B, B = \{S, Q, L\}$

4. Weight together the components from steps 1-3

The key assumptions involved in the simulation procedure concerns step 2. Here we assume that uncertainty about time spent out of work is resolved at the beginning of the month. There are three different parts to earnings in 2021 if a job transition occurs. The first part is earnings **before** the separation. We assume that workers get a proportional amount of earnings from the staying branch earnings.¹ To implement this, we draw earnings from the stay earnings distribution and normalize the annual earnings by the duration of this spell. The second part is **job search period** before the reemployment. We assume zero earned earnings in this search period. Finally, the third part is **after** reemployment. We draw an annual earnings from their conditional earnings distribution after reemployment in the branch. We adjust the annual earnings from this new employer by the number of months in the new job 2021.

Figure D.1 shows an example of how we simulate the earnings in 2021 following lay-off. When a lay-off occurs in step 1 then we draw a month for the job separation event after solving the equations (1)-(2). In the example, March is selected. In this case, the

¹If they have zero stay probability, we impute their earned earnings in the last year. However, 98.5% of workers have a positive probability of staying with their current employer.

Note: The figure shows the average value of the 2nd to 4th standard moments over the life cycle of holistic earnings risk, g_i , and risk conditional on staying, f_i^S . “o” and “x” represent the empirical mean across 5-years age bins. The lines are local linear polynomials, calculated using a bandwidth of 4 years. Survey results are weighted using population weights.

Figure C.8: Moments of holistic earnings risk, g_i , vs. risk conditional on staying, f_i^S , over the life cycle: using standard moments

individual will receive a monthly wage for January and February, and we pick that from the stay branch’s earnings distribution f_i^S . For the purpose of illustration, assume that \$ 120 is randomly drawn from f_i^S . We normalize this by multiplying $\frac{2}{12}$ to reflect the fraction of the year. In the example, July is chosen as the reemployment month as a result of simulating the reemployment distribution. Therefore, from March to June this individual has 0 earnings. Lastly, from July to December, the individual will receive a salary from the new employer and we, therefore, draw an earnings realization from her conditional earnings distribution, f_i^L , in this case \$100. We normalize this by $\frac{6}{12}$ to reflect the fraction of the year spent in the new job. Therefore, in this simulation, the aggregated earned earnings in 2021 is \$70.

E Moments of the Pooled Distribution

E.1 Age Group and Current Earnings Variations

In this section, we report figures corresponding to Figure 8 in the paper for all the groups defined in section 4.1. We note again that we divide the sample into two earnings groups, above-median (high) and below-median (low), and three broad age groups (20-34, 35-49, 50-65). Figure E.1 shows the results. The number on the label shows their age group and High/Low means their earnings level in the age group. Across all age groups and earnings levels, we find a pattern consistent with the pattern presented in Figure 8 in the paper. We confirm that the administrative based measure, h_A^X , and survey based measure, h_S^X , are well aligned. On the other hand, the subjective measure, g_i , is heterogeneous while being centered around 0.

Note: Estimates of the mean for h_S^X , h_A^X , and the distribution of g_i for four subgroups in the data.

Figure E.1: Mean of h_S^X and h_A^X , and the distributions of individual means of g_i for four selected subgroups

Figure E.2 show the distribution of the interdecile range, $p_{90} - p_{10}$, across groups. We again find that the subjective g_i is systematically lower compared to the registry and survey pooled moments.

Note: Estimates of the interdecile range for h_S^X , h_A^X , and the distribution of g_i for four subgroups in the data.

Figure E.2: Interdecile range of h_S^X and h_A^X , and the distributions of individual interdecile range of g_i for four selected subgroups

E.2 Derivations

Referring back to equation (4) in the main text, let $m^{(k)}$ be the k^{th} moment of h_S^X and let $m_i^{(k)}$ be the k^{th} moment of g_i , then each moment of a mixture distribution of N equally weighted distributions is given by the convex combination

$$m^{(k)} = \frac{1}{N} \sum_i^N m_i^{(k)} \quad (3)$$

and the variance (the centralized second moment) is given by

$$\begin{aligned} \text{Var}(h) &= m^{(2)} - \left(m^{(1)}\right)^2 \\ &= \frac{1}{N} \sum_i^N m_i^{(2)} - \left(\frac{1}{N} \sum_i^N \mu_i\right)^2 \\ &= \frac{1}{N} \sum_i^N (\sigma_i^2 + \mu_i^2) - \left(\frac{1}{N} \sum_i^N \mu_i\right)^2 \\ &= \frac{1}{N} \sum_i^N \sigma_i^2 + \frac{1}{N} \sum_i^N \mu_i^2 - \left(\frac{1}{N} \sum_i^N \mu_i\right)^2 \end{aligned} \quad (4)$$

The sum of the last two terms is always non-negative by Jensen's Inequality and increasing in dispersion in the μ_i 's. This means that differences in the individual μ_i 's increases the variance of h .

The skewness (the centralized third moment) is given by

$$\begin{aligned} \text{Skew}(h) &= m^{(3)} - 3m^{(1)}m^{(2)} + 2\left(m^{(1)}\right)^3 \\ &= \frac{1}{N} \sum_i^N m_i^{(3)} - 3\frac{1}{N} \sum_i^N m_i^{(1)} \frac{1}{N} \sum_i^N m_i^{(2)} + 2\left(\frac{1}{N} \sum_i^N m_i^{(1)}\right)^3 \\ &= \frac{1}{N} \sum_i^N (\gamma_i^3 + 3\sigma_i^2\mu_i + 3\mu_i^3) - \frac{3}{N^2} \sum_i^N \mu_i \sum_i^N (\sigma_i^2 + \mu_i^2) + \frac{2}{N^3} \left(\sum_i^N \mu_i\right)^3 \end{aligned} \quad (5)$$

where γ_i^3 is the skewness of g_i and we use equation (3) to convert $m^{(k)}$ to $m_i^{(k)}$ that are given by

$$\begin{aligned} m_i^{(1)} &= \mu_i \\ m_i^{(2)} &= \sigma_i^2 + \mu_i^2 \\ m_i^{(3)} &= \gamma_i^3 + 3\mu_i(\sigma_i^2 + \mu_i^2) - 2\mu_i^3 \\ &= \gamma_i^3 + 3\sigma_i^2\mu_i + 3\mu_i^3 \end{aligned} \quad (6)$$

From Equation (5) we see that $\text{Skew}(h)$ is the average of the individual skewness (γ_i^3 , first term of first sum) in addition to an ambiguous dependence on the individual means and variances.

Kurtosis (the centralized fourth moment) is given by

$$\begin{aligned}
\text{Kurt}(h) &= m^{(4)} - 4m^{(1)}m^{(3)} + 6\left(m^{(1)}\right)^2 m^{(2)} - 3\left(m^{(1)}\right)^4 \\
&= \frac{1}{N} \sum_i m_i^{(4)} - 4\frac{1}{N} \sum_i m_i^{(1)} \frac{1}{N} \sum_i m_i^{(3)} + \\
&\quad 6\left(\frac{1}{N} \sum_i m_i^{(1)}\right)^2 \frac{1}{N} \sum_i m_i^{(2)} + 3\left(\frac{1}{N} \sum_i m_i^{(1)}\right)^4 \\
&= \frac{1}{N} \sum_i \left(\kappa_i^4 + 4\gamma_i^3 \mu_i + 6\sigma_i^2 \mu_i^2 + \mu_i^4\right) - \frac{4}{N^2} \sum_i \left(\gamma_i^3 + 2\sigma_i^2 \mu_i + \mu_i^3\right) + \\
&\quad \frac{6}{N^3} \left(\sum_i \mu_i\right)^2 \left(\sum_i \sigma_i^2 + \mu_i^2\right) + \frac{3}{N^4} \sum_i (\mu_i)^4
\end{aligned} \tag{7}$$

where κ_i^4 is the kurtosis of g_i and in addition to equation (6) we use that

$$\begin{aligned}
m_i^{(4)} &= \kappa_i^4 + 4m_i^{(1)}m_i^{(3)} - 6\left(m_i^{(1)}\right)^2 m_i^{(2)} + 3\left(m_i^{(1)}\right)^4 \\
&= \kappa_i^4 + 4\mu_i \left(\gamma_i^3 + 3\mu_i \left(\sigma_i^2 + \mu_i^2\right) - 2\mu_i^3\right) - 6\mu_i^2 \left(\sigma_i^2 + \mu_i^2\right) + 3\mu_i^4 \\
&= \kappa_i^4 + 4\gamma_i^3 \mu_i + 6\sigma_i^2 \mu_i^2 + \mu_i^4
\end{aligned} \tag{8}$$

From Equation (7) we see that $\text{Kurt}(h)$ is the average of the individual kurtosis (κ_i^4 , first term of first sum) in addition to an ambiguous dependence on the individual means, variances and skewnesses.

E.3 Subjective and Registry Earnings Risk, Skewness and Kurtosis

Figure E.3 (a) shows the relationship between skewness of the h_A^X , i.e., skewness inferred from the administrative data in cell X , and average skewness of the subjective holistic distributions g_i . As shown above, the relationship between these two measures is ambiguous. In practice the two measures turn out to be unrelated. The correlation is -0.05 and insignificant at the 10% level of significance. Panel (b) shows the relationship between kurtosis of h_A^X , i.e., kurtosis inferred from the administrative data in cell X and average kurtosis of the subjective holistic distributions g_i in the same X cells. These two measures turn out to be weakly related with an estimated slope parameter of 0.11 which is not

significant at the 10 % level. This is consistent with the theoretical prediction derived in the previous subsection showing that the relationship between the two measures is ambiguous.

Note: The figure compares average skewness and kurtosis of subjective holistic earnings expectations, g_i , to those calculated from administrative data. Both are calculated within 300 cells divided by age group and within age group earnings percentiles, h_A^X , i.e, the same partition applied in the construction of Figure 9 in the paper. The panels show binned scatterplots (red circles) where the bins represent vigintiles of the interdecile range calculated from the administrative data. A regression line based on the 300 data points is overlaid.

Figure E.3: Comparing skewness and kurtosis calculated from subjective expectations and from administrative data

E.4 Subjective and Registry Earnings Risk, Finer X -cells

In this subsection, we construct registry based earnings risk using a more detailed partition based on demographics. We partition the administrative data based on age, gender, education, and earnings deciles and calculate registry based moments within each of these cells. In total, we have 1,800 cells, i.e., a substantially more detailed stratification than the one applied in the paper which divides the data into 300 cells. Based on this we do a similar exercise as in Figure 9 of the main text. Figure E.4 shows the result. The pattern is very similar to the pattern shown in Figure 9 in the paper.

E.5 Subjective and Registry Earnings Risk, Heterogeneous Income Profiles (HIP)

The literature examining heterogeneous income processes (HIP) assumes that individual-level heterogeneity in earnings growth is present. To address this issue we calculate average individual level earnings growth over the last 5 years (2016-2020). We then divide the sample into cells by age, gender, education, current earnings quintiles, and last

Note: The figure compares average interdecile range, $p_{90} - p_{10}$, of subjective holistic earnings expectations, g_i , to interdecile range calculated from administrative data. Both are calculated within 1,800 cells divided by age, gender, education, and earnings deciles, h_A^X . The panel shows a binned scatterplot (red circles) where the bins represent vigintiles of the interdecile range calculated from the administrative data. A regression line based on the 1,800 data points is overlaid.

Figure E.4: Comparing interdecile ranges calculated from subjective expectations and from administrative data: finer X -cells

5 years' average earnings growth quintiles, resulting in 4,500 cells over which we conduct an exercise similar to the one presented in Figure 9 in the paper. Again, the results are practically identical to the results presented in Figure E.5.

Note: The figure compares average interdecile range, $p_{90}-p_{10}$, of subjective holistic earnings expectations, g_i , to interdecile range calculated from administrative data. Both are calculated within 4,500 cells divided by age, gender, education, current earnings quintiles, and last 5 years' average earnings growth quintiles, h_A^X . The panel shows a binned scatterplot (red circles) where the bins represent vigintiles of the interdecile range calculated from the administrative data. A regression line based on the 4,500 data points is overlaid.

Figure E.5: Comparing interdecile ranges calculated from subjective expectations and from administrative data: HIP

F Consumption Savings Model

F.1 Estimating Earnings Process Parameters

In this section, we describe the estimation procedure for the parameters of the earnings process in Section 6 in the paper. We start by constructing relevant moments based on the two-parameter earnings process from the main text, where Δy_t^i (which equals $y_t^i - y_{t-1}^i$) represents the earnings growth for individual i at time t . Then, we can write two-moment conditions as a function of two parameters. The first moment condition on the left-hand side corresponds to the cross-sectional variance of earnings growth, while the second corresponds to the covariance of earnings growth. Then, there are two unknowns ($\sigma_\eta^2, \sigma_\epsilon^2$) with two equations, so we can identify the parameters.

$$\begin{aligned} Var(\Delta y_t^i) &= \sigma_\eta^2 + 2\sigma_\epsilon^2 \\ Cov(\Delta y_t^i, \Delta y_{t-1}^i) &= -\sigma_\epsilon^2 \end{aligned} \tag{9}$$

To construct empirical moments, we use registry data and restrict the sample to include those with earnings above 20,000 DKK from 2018 to 2020 and age between 20 and 65. We first run a regression using age, age-sq, gender, education above college, and year-fixed effect to obtain the residualized log earnings. Then, using residual log earnings, we construct earnings growth and the moment values for the left-hand side of Equation (9).

F.2 Retirement Phase

In this subsection, we provide details about the specification of retirement income and corresponding value functions. Income during retirement replaces R percent of earnings in the last period before retirement y_T^i and with a guaranteed social security floor, $\underline{ss}$ such that retirement income is $y_R^i = \max\{R \times y_T^i, \underline{ss}\}$. There is no uncertainty on retirement income, and they get a fixed amount.

The value function for retired workers is as follows.

$$\begin{aligned} V_t^i(x_t^i, ss^i) &= \max_{c_t^i, a_{t+1}^i} \left\{ \frac{(c_t^i)^{1-\phi}}{1-\phi} + \delta[V_t^i(x_t^i, ss^i)] \right\} \\ \text{s.t.} \quad c_t^i + a_{t+1}^i &= x_t^i \\ x_t^i &= (1+r)a_t^i + exp(y_R^i) \\ y_R^i &= \max\{R \times y_T^i, \underline{ss}\} \end{aligned} \tag{10}$$

for $t = T, \dots, L$ with $V_{L+1} = 0$.

We use R as 0.8 and $\underline{ss}$ as 140,000 DKK, corresponding to 20,000 USD for the simulation.

F.3 Distribution of α_i^K and $\mu_{g,i}^K$

In this subsection, we report the value of α_i^K and $\mu_{g,i}^K$ we used in each simulation. Table F.1 shows the value of α_i^K and $\mu_{g,i}^K$ we used for Survey 3-G and 10-G.

Table F.1: The values of α_i^K and $\mu_{g,i}^K$

G	A. α_i^K		B. $\mu_{g,i}^K$	
	Survey 3-G	Survey 10-G	Survey 3-G	Survey 10-G
