N
United States
Department
of Labor

Unemployment rose sharply in April and employment declined for the second month in a row, the Bureau of Labor Statistics of the U.S. Department of Labor reported today. The April unemployment rate was 7.0 percent, up from 6.2 percent in March. The number of persons umemployed increased by 825,000 over the month and was up nearly 1.2 million from December

Total employnent--as measured by the nonthly survey of households--was down 500,000 in April, following a decifine of $\mathbf{3 0 0 , 0 0 0}$ in the previous month. At 97.2 million, total employment has fallen back to the levels which prevalled during the sumaer of 1979.

Nonfarm payroll employment--as measured by the monthly survey of establishments--dropped by $480,000 \mathrm{in}$ April to 90.3 million. The decrease was concentrated in the manufacturing, construction, and trade industries. Average weekly hours also declined over the month.

## Unemployment

In April, the unemployment rate rose 0.8 percentage point to 7.0 percent, the highest rate since Auguat 1977. The number of unemployed increased by 825,000 to 7.3 million. Unemployment increased for nearly all worker groups, including adults, full-time workers, whitea, and blacks. The unemployment rate for adult men rose a full percentage point to 5.9 percent; the rate for adult women moved up from 5.7 to 6.3 percent. (See table A-2.)

Unemployment increases were particularly large for workers in construction and durable goods manufacturing. Similarly, unemployment rates in the blue-collar occupations were up markediy in April, with operatives and craft workers registering the most sizeable increases. (See table A-2.)

Job losers (including persons on layoff and those whose jobs were terminated) led the unemployment increase and, in April, constituted half of all unemployed workers. There were amaller, though substantial, increases in the number of unemployed who had voluntarily left their last job and in the number who were reentering the labor force after a period of absence. Average duration of unemployment was about unchanged, as increases occurred not only in the
number of workers recently out of work but also in the number who had been fobless for longer periods of time. (See tables A-5 and A-4.)

The number of nonfarn workers on part-time work schedules for economic reasons (sometimes termed the "partialiy unemployed") increased by 400,000 in April to 3.8 million. Nore than 60 percent of the increase was among those who usually worked full time. (See table A-3.)

## Employment

Total employment fell by 500,000 in April, and the 2 -month decifne totaled 800,000 workers. These decreases were most pronounced among adult men, whose employment level dropped by 430,000 In April and by 660,000 over the 2 month period. On an occupational basis, the largest

over-the-month employment decline occurred among blue-collar workers. Since April 1979, total employment has risen by only 890,000 or less than 1 percent. (See tables $A-1$ and A-3.)

With the large decline in employment, the overall employment-population ratio fell 0.4 percentage point over the month to 58.6 percent. The corresponding ratio for adult men dropped from 73.8 to 73.1 percent.

The civilian labor force rose by 325,000 in April to 104.4 million. The labor force participation rate edged upward, to 63.8 percent. Most of the labor force inctease occurred atuong adult women.

## Industry Payroll Employment

Nonagricultural payroll employment declined by 480,000 in April to 90.3 arllion. This was the largest over-the-month reduction since December 1974.

The decine was concentrated in the goods-producing sector, with durable goods manufacturing and construction bearing the brunt of the cutbscks. Enployment in the durable goods induatries fell by 265,000 , with over half occurring in transportation equipment, mainly in automobile production. Sizeable declines were also posted in fabricated netals, lunber and wood products, and stone, clay, and glass products. Employment changes in the nondurable goods industries were generally small. (See table B-1.)

Employment in construction dropped 140,000 in April following a decline of like magnitude in the previous month. This industry has lost 335,000 jobs since January.

In the service-producing sector, employment fell by 130,000 in trade; an additional 30,000 job decifne occurred in transportation and publif utilities. On the other hand, goverment employment was up 75,000 in April, on top of a 60,000 increase in March; both gains were due primarily to the hiring of temporary workers for the 1980 Census.

## Hours of Work

The average workweek for production or nonsupervisory workers on private nonagricultural payrolls edged down 0.1 hour to 35.3 hours in April; average weekly hours have fallen for 3 consecutive months. The manufacturing workweek, at 39.6 hours $i_{1}$ April, dropped 0.2 hour aver the month and was down 0.7 hour since January. Factory overtime declined 0.3 hour in April to 2.8 hours. (See table B-2.)

Matnly due to the large employment cutback, the index of aggregate weekly hours of production or nonsupervisory workers on private nonfatim payrolla fell 1.3 percent to 124.5 (1967-100) in April. The manufacturing index dropped 2.4 percent over the month. Whereas the overall index was up slightly over the past year, the factory Index was down 2.6 percent. (See table B-5.)

## Hourly and Weekly Earnings

Average hourly earnings of production or nonsupervisory workers on private nonagricultural payrolls were unchanged over the month and were 7.9 percent above the April 1979 level (seasonally adjusted). Average weekly earnings declined by 0.3 percent from March but were up 7.9 percent over the year.

Before adjustment for seasonality, average hourly earnings were unchanged over the month at \$6.51, 48 cents above April a year ago. Average weekly earnings declined by 65 cente over the month to $\$ 228.50$; shis level was $\$ 16.85$ above a year ago. (See table B-3.)

## The Hourly Earnings Index

The Hourly Earnings Index--earnings adjusted for overtime in manufacturing, seasonality, and the effects of changes in the proportion of workers in high-wage and low-wage indurtries-was 245.6 ( $1967=100$ ) in Apri1, 0.2 percent higher than in March. The Index was 8.3 percent abova April a year ago. In dollars of constant purchasing power, the Index decreased 5.0 percent during the 12 -month period ended in March. (See table B-4.)

## Explanatory Note

This news release presents statistics from two major Surveys, the Current Population Survey (household survey) and the Current Employment Statistics Survey (estabishment survey). The household survey provides the information on the labor force, total employment, and unemployment that appears in the A tables, marked
HOUSEHOLD DATA. It is a sample survey of about 65,000 households that is conducted by the Bureau of the Census with most of the findings analyzed and published by the Bureau of Labor Statistics (BLS).
The establishment survey provides the information on the employment, hours, and earnings of workers on nonagricultural payrolls that appears in the B tables, marked ESTABLISHMENT DATA. This information is collected from payroll records by BLS in cooperation with State agencies. The sample includes approximately 162,000 establishments employing more than 32 million $\stackrel{\text { people. }}{\text { For bo }}$
For both surveys, the data for a given month are actually collected for and relate to a particular week. In the calendar week that contains the 12 th day of the month, which is called the survey week. In the establishment survey, the reference week is the pay period including the 12 th, which may or may not correspond directly to the calendar week.
The data in this release are affected by a number of technical factors, including definitions, survey differences, seasonal adjustments, and the inevitable
variance in results between a survey of a sample and a census of the entire population. Each of these factors is explained below.

Coverage, definitions and differences between surveys The sample households in the household survey are selected so as to reflect the entire civilian noninstitutional population 16 years of age and older. Each person in a household is classified as employed, unemployed, or not in the labor force. Those who hold more than one job are classified according to the job at phich they worked the most hours.
all as paid civilians; worked in their own business or profession or on their own farm; or worked 15 hours or more in an enterprise operated by a member of their family, whether they were paid or not. People are also counted as employed if they were on unpaid leave because of illness, bad weather, disputes between labor and management, or personal reasons.
their eligibibity for unemployment benefits or public assistance, if they meet all of the following criteria: They had no employment during the survey week; they were available for work at that time; and they made specific efforts to find employment sometime during the
prior 4 weeks. Also included among the unemployed are prior 4 weeks. Also included among the unemployed are
persons not looking for work because they were laid off
and waiting to be recalled and those expecting to repor to a job within 30 days.
The civilian labor force equals the sum of the number ment rate is the percentage of unemployed people in the civilian labor force. Table A-4 presents a special group ing of seven measures of unemployment based on varying definitions of unemployment and the labor force. The definitions are provided in the table. The most restrictive definition yields U-1, and the most comis P U-S. S . U-S.
Unive the household survey, the establishmen names anpear on the payroll and salary employees whose firms. As a result, there are many differences between he two surveys, among which are the following.
-...The household survey, although based on a smaller sample, reflects a larger segment of the population; the establishment survey excludes agriculture, the self-employed, unpaid family workers, and privat household workers;
includes people on unpaid the employed; the establishment survey --The
athe household is limited to those 16 years by age; dividuals, houschold survey has no duplication of individuals, because each individual is counted only once; than one job or otherwise appearing on mork tha more payroll would be counted separately for eash appearance.
Other differences between the two surveys are described in "Comparing Employment Estimates from Household and Payroll Surveys," which may be obtain ed from the BLS upon request.

## Seasonal adjustment

Over a course of a year, the size of the Nation's labo force and the levels of employment and unemploymen undergo sharp fluctuations due to such seasonal event as changes in weather, reduced or expanded production harvests, major hoiidays, and the opening and closing schools. For example, the labor force increases by a oung people each June, when schools close and many seasonal variation can be very large: over the course of a year for example can be very large; over the course of as 95 percent of the mon may account for as much as 95 percent
Because these seasonal events follow a more or less regular pattern each year, their influence on statistical trends can be eliminated by adjusting the statistics from month to month. These adjustments make nonseasonal developments, such as declines in economic activity or
increases in the participation of women in the labor force, easier to spot. To return to the school's-out example, the large number of people entering the labor force each June is likely to obscure any other changes that have taken place since May, making it difficult to determine if the level of economic activity has risen or declined. However, because the effect of students finishing school in previous years is known, the statistics for the current year can be adjusted to allow for a comparable change. Insofar as the seasonal adjustment is made correctly, the adjusted figure provides a more useful tool with which to analyze changes in economic activity.

Measures of civilian labor force, employment, and unemployment contain components such as age and sex. Statistics for all employees, production workers, average weekly hours, and average hourly earnings include components based on the employer's industry. All these statistics can be seasonally adjusted either by adjusting the total or by adjusting each of the components and combining them. The second procedure usually yields more accurate information and is therefore followed by BLS. For example, the seasonally adjusted figure for the civilian labor force is the sum of eight seasonally adjusted employment components and four seasonally adjusted unemployment components; the total for unemployment is the sum of the four unemployment components; and the official unemployment rate is derived by dividing the resulting estimate of total unemployment by the estimate of the civilian labor force.

The numerical factors used to make the seasonal adjustments are recalculated regularly. For the household survey, the factors are calculated for the January-June period and again for the July-December period. The January revision is applied to data that have been published over the previous 5 years. For the establishment survey, updated factors for seasonal adjustment are calculated only once a year, along with the introduction of new benchmarks which are discussed at the end of the next section.

## Sampling variability

Statistics based on the household and establishment surveys are subject to sampling error, that is, the estimate of the number of people employed and the other estimates drawn from these surveys probably differ from the figures that would be obtained from a complete census, even if the same questionnaires and procedures were used. In the household survey, the amount of the differences can be expressed in terms of standard errors. The numerical value of a standard error depends upon the size of the sample, the results of the survey, and other factors. However, the numerical value is always such that the chances are 68 out of 100 that an estimate based on the sample will differ by no more than the standard error from the results of a complete census. The chances are 90 out of 100 that an estimate based on the sample will differ by no more than 1.6 times the
standard error from the results of a complete census. At the 90 -percent level of confidence--the confidence limits used by BLS in its analyses--the error for the monthly change in total employment is on the order of plus or minus 293,000; for total unemployment, it is 185,000 ; and, for the overall unemployment rate, it is 0.19 percentage point. These figures do not mean that the sample results are off by these magnitudes but, rather, that the chances are 90 out of 100 that the "true" level or rate would not be expected to differ from the ecimates by more than these amounts.

Sampling errors for monthly surveys are reduced when the data are cumulated for several months, such as quarterly or annually. Also, as a general rule, the smaller the estimate, the larger the sampling error. Therefore, relatively speaking, the estimate of the size of the labor force is subject to less error than is the estimate of the number unemployed. And, among the unemployed, the sampling error for the jobless rate of adult men, for example, is much smaller than is the error for the jobless rate of teenagers. Specifically, the error on monthly change in the jobless rate for men is .23 percentage point; for teenagers, it is 1.06 percentage points.

In the establishment survey, estimates for the 2 most current months are based on incomplete returns; for this reason, these estimates are labeled preliminary in the tables. When all the returns in the sample have been received, the estimates are revised. In other words, data for the month of September are published in preliminary form in October and November and in final form in December. To remove errors that build up over time, a comprehensive count of the employed is conducted each year. The results of this survey are used to establish new benchmarks-comprehensive counts of employment-against which month-to-month changes can be measured. The new benchmarks also incorporate changes in the classification of industries and allow for the formation of new establishments.

## Additional statistics and other information

In order to provide a broad view of the Nation's employment situation, BLS regularly publishes a wide variety of data in this news release. More comprehensive statistics are contained in Employment and Earnings, published each month by BL.S. It is available for $\$ 2.75$ per issue or $\$ 22.00$ per year from the U.S. Government Printing Office, Washington, D.C. 20204. A check or money order made out to the Superintendent of Documents must accompany all orders.

Employment and Earnings also provides approximations of the standard errors for the houschold survey data published in this release. For unemployment and other labor force categories, the standard errors appear in tables A through I of its "Explanatory Notes." Measures of the reliability of the data drawn from the establishment survey and the actual amounts of revision due to benchmark adjustments are provided in tables $\mathbf{K}$ through $P$ of that publication.

pepretiminary.
NOTE: All series are in current doilars except where indicated. The index excludes effects of two types of changes that are unrelated to underlying wage-rate developments: Fluctuations in overtime premiums in manufacturing the only sector for which overtime date are available) and the effects of changes in the proportion of workers in high-wage and low-wage industries.
