TRANSMISSION OF MATERIAL IN THIS RELEASE IS EMBARGOED UNTIL
8:30 A.M. (EST), FRIDAY, APRIL 5, 1985

## THE EMPLOYMENT SITUATION: MARCH 1985

Employment rose markedly in March, and unemployment was unchanged, the Bureau of Labor Statistics of the U.S. Department of Labor reported today. The overall unemployment rate of 7.2 percent and the civilian worker rate of 7.3 percent were both the same as in February.

Civilian employment--as measured by the monthly survey of households--totaled 107.1 million in March, up 430,000 over the month. At 60.3 percent, the proportion of the civilian population with jobs was the highest ever recorded.

The number of persons on nonagricultural payrolls--as measured by the establishment survey--advanced by 380,000 . Strong job growth continued in the service-producing sector, while manufacturing employment was little changed.

## Unemployment (Household Survey Data)

The seasonally adjusted level of unemployment, 8.4 million workers, did not change from February to March. Similarly, the March unemployment rates of 7.2 percent for the labor force including the resident Armed Forces, and 7.3 percent for civilian workers only, were unchanged over the month. Unemployment has been little changed since last autumn, after declining sharply from the recession high of late 1982.

Unemployment rates for adult men (6.2 percent), adult women (6.7 percent), and teenagers ( 18.2 percent) were either the same or virtually unchanged over the month. After rising in February, the unemployment rate for black workers fell 1.1 percentage points to 15.2 percent, about the same as the rates prevailing in the September-January period. The white unemployment rate remained at 6.2 percent, and the rate for workers of Hispanic origin was little changed at 10.2 percent. (See tables A-2 and A-3.)

The median duration of unemployment was little changed over the month at 7.1 weeks, and the average (mean) duration held at 15.9 weeks. The number unemployed for more than 6 months remained at 1.3 million. (See table A-7.)

```
Civilian Employment and the Labor Force (Household Survey Data)
```

Civilian employment rose by 430,000 in March to a seasonally adjusted level of 107.1 million, and the employment-population ratio reached a new
record of 60.3 percent. Most of the employment advance occurred among adult women, as their employment total rose by a quarter of a million to 44.0 million. Over the year, the number of employed persons rose by 3.0 million; adult women accounted for 56 percent of this gain, adult men 36 percent, and teenagers the remainder. (See table A-2.)

Table A. Major indicators of labor market activity, seasonally adjusted

The civilian labor forçe also rose by 430,000 in March, reaching a level of 115.5 million. This increase was also concentrated among adult women, whose labor force participation rate continued to set new records. The labor force increased by 2.6 million over the year.

## Discouraged Workers (Household Survey Data)

In the first quarter of 1985, there were 1.3 million discouraged workers--persons who report that they want to work but had not actively sought a job during the previous 4-week period because they thought they could not find one. Nearly one-third of the discouraged total cited personal factors such as age or lack of training; the remainder cited job market factors. The number of discouraged workers has come down very little in the past year, following a decline of about half a million from the recession high. (See table A-13.)

## Industry Payroll Employment (Establishment Survey Data)

Total nonagricultural payroll employment rose by 380,000 in March to 96.5 miliion, after adjustment for seasonality. The bulk of the job growth occurred in the service-producing sector, with particularly strong advances in services $(145,000)$ and retail trade $(80,000)$. Over the past year, these two industry divisions have accounted for more than half of the total payroll employment expansion of 3.4 million. Over-the-month increases also took place in wholesale trade and finance, insurance, and real estate. (See table B-1.)

Construction employment increased by 130,000 after seasonal adjustment, more than offsetting a weather-induced decline that took place in February. The March employment level was a record 4.6 million, 90,000 above January and up by more than 400,000 from a year earlier.

In contrast, manufacturing employment was little changed in March, following a decline in the prior month. Over-the-month movements among individual manufacturing industries were generally small and somewhat offsetting, although motor vehicle jobs have declined by 35,000 since January. After recovering about three-quarters of the jobs lost during the recession, there has been no net growth in total factory jobs since last summer.

## Weekly Hours (Establishment Survey Data)

The average workweek of production or nonsupervisory workers on private nonagricultural payrolls edged up 0.1 hour in March to 35.1 hours. The manufacturing workweek rose by half an hour to 40.4 hours, nearly recouping the weather-related cutbacks that occurred in February. Factory overtime hours remained unchanged at 3.3 hours. (See table B-2.)

The index of aggregate weekly hours of production or nonsupervisory workers on private nonfarm payrolls rose by 0.7 percent in March to 115.0 ( $1977=100$ ), reflecting the increase in both employment and hours. The
manufacturing index increased 1.0 percent over the month to 95.4 but was still below the levels which had prevailed throughout most of 1984. (See table B-5.)

## Hourly and Weekly Earnings (Establishment Survey Data)

Average hourly earnings increased 0.5 percent in March, and average weekly earnings increased 0.8 percent, seasonally adjusted. Before adjustment for seasonality, average hourly earnings rose 1 cent to $\$ 8.53$, and weekly earnings increased by $\$ 2.06$ to $\$ 297.70$. Compared to a year earlier, hourly earnings were up 29 cents, and weekly earnings rose by \$9.30. (See table B-3.)

## The Hourly Earnings Index (Establishment Survey Data)

The Hourly Earnings Index (HEI) was 164.4 (1977=100) in March, seasonally adjusted, an increase of 0.4 percent from February. For the 12 months ended in March, the increase (before seasonal adjustment) was 3.3 percent. The HEI excludes the effects of two types of changes unrelated to underlying wage rate movements--fluctuations in overtime in manufacturing and interindustry employment shifts. In dollars of constant purchasing power, the HEI decreased 0.1 percent during the 12 -month period ended in February. (See table B-4.)

## Explanatory Note

This news release presents statistics from two major surveys, the Current Population Survey (household survey) and the Current Employment Statistics Survey (establishment survey). The household survey provides the information on the labor force, total employment, and unemployment that appears in the A tables, marked HOUSEHOLD DATA. It is a sample survey of about 59,500 households that is conducted by the Bureau of the Census with most of the findings analyzed and published by the Bureau of Labor Statistics (BLS).

The establishment survey provides the information on the employment, hours, and earnings of workers on nonagricultural payrolls that appears in the B tables, marked ESTABLISHMENT DATA. This information is collected from payroll records by BLS in cooperation with State agencies. The sample includes over $\mathbf{2 0 0 , 0 0 0}$ establishments employing over 35 million people.

For both surveys, the data for a given month are actually collected for and relate to a particular week. In the household survey, unless otherwise indicated, it is the calendar week that contains the 12th day of the month, which is called the survey week. In the establishment survey, the reference week is the pay period including the 12 th, which may or may not correspond directly to the calendar week.

The data in this release are affected by a number of technical factors, including definitions, survey differences, seasonal adjustments, and the inevitable variance in results between a survey of a sample and a census of the entire population. Each of these factors is explained below.

## Coverage, definitions, and differences between surveys

The sample households in the household survey are selected so as to reflect the entire civilian noninstitutional population 16 years of age and older. Each person in a household is classified as employed, unemployed, or not in the labor force. Those who hold more than one job are classified according to the job at which they worked the most hours.

People are classified as employed if they did any work at all as paid civilians; worked in their own business or profession or on their own farm; or worked 15 hours or more in an enterprise operated by a member of their family, whether they were paid or not. People are also counted as employed if they were on unpaid leave because of illness, bad weather, disputes between labor and management, or personal reasons. Members of the Armed Forces stationed in the United States are also included in the employed total.

People are classified as unemploved, regardless of their eligibility for unemployment benefits or public assistance, if they meet all of the following criteria: They had no employment during the survey week; they were available for work at
that time; and they made specific efforts to find employment sometime during the prior 4 weeks. Also included among the unemployed are persons not looking for work because they were laid off and waiting to be recalled and those expecting to report to a job within 30 days.

The labor force equals the sum of the number employed and the number unemployed. The unemployment rate is the percentage of unemployed people in the labor force (civilian plus the resident Armed Forces). Table A-5 presents a special grouping of seven measures of unemployment based on varying definitions of unemployment and the labor force. The definitions are provided in the table. The most restrictive definition yields $\mathrm{U}-1$ and the most comprehensive yields U-7. The overall unemployment rate is $\mathrm{U}-5 \mathrm{a}$, while $\mathrm{U}-5 \mathrm{~b}$ represents the same measure with a civilian labor force base.

Unlike the household survey, the establishment survey only counts wage and salary employees whose names appear on the payroll records of nonagricultural firms. As a result, there are many differences between the two surveys, among which are the following:

- The household survey, although based on a smaller sample, reflects a larger segment of the population; the establishment survey excludes agriculture, the self-employed, unpaid family workers, private household workers, and members of the resident Armed Forces;
- The household survey includes people on unpaid leave among the employed; the establishment survey does not;
-- The household survey is limited to those 16 years of age and older; the establishment survey is not limited by age:
- The houvehold survey has no duplication of individuals, because each indurdual w counted only once; in the establishment survey, employees working at more than one job or otherwise appearing on more than one payroll would be counted separately for each appearance.

Other differences between the two surveys are described in "Comparing Employment Estimates from Household and Payroll Surveys," which may be obtained from the BIS upon request.

## Seasonal adjustment

Over the course of a year, the size of the Nation's labor force and the levels of employment and unemployment undergo sharp fluctuations due to such seasonal events as changes in weather, reduced or expanded production, harvests, major holidays, and the opening and closing of schools. For example, the labor force increases by a large number each June, when schools close and many young people enter the job market. The effect of such seasonal variation can be very large; over the course of a year, for example, seasonality may account for as much as 95 percent of the month-to-month changes in unemployment.

Because these seasonal events follow a more or less regular pattern each year, their influence on statistical trends can be eliminated by adjusting the statistics from month to 'month. These adjustments make nonseasonal developments, such as declines in economic activity or increases in the participation of women in the labor force, easier to spot. To return to the school's-out example, the large number of people entering the labor force each June is likely to obscure any other changes that have taken place since May, making it difficult to determine if the level of economic activity has risen or declined. However, because the effect of students finishing school in previous years is known, the statistics for the current year can be adjusted to allow for a comparable change. Insofar as the seasonal adjustment is made correctly, the adjusted figure provides a more useful tool with which to analyze changes in economic activity.

Measures of labor force, employment, and unemployment contain components such as age and sex. Statistics for all employees, production workers, average weekly hours, and average hourly earnings include components based on the employer's industry. All these statistics can be seasonally adjusted either by adjusting the total or by adjusting each of the components and combining them. The second procedure usually yields more accurate information and is therefore followed by bls. For example, the seasonally adjusted figure for the labor force is the sum of eight seasonally adjusted civilian employment components, plus the resident Armed Forces total (not adjusted for seasonality), and four seasonally adjusted unemployment components; the total for unemployment is the sum of the four unemployment components; and the overall unemployment rate is derived by dividing the resulting estimate of total unemployment by the estimate of the labor force.

The numerical factors used to make the seasonal adjustments are recalculated regularly. For the household survey, the factors are calculated for the January-Ju:? period and again for the July-December period. The January revision is applied to data that have been published over the previous 5 years. For the establishment survey, updated factors for seasonal adjustment are calculated only once a year, along with the introduction of new benchmarks which are discussed at the end of the next section

## Sampling variability

Statistics based on the household and establishment surveys are subject to sampling error, that is, the estimate of the number of people employed and the other estimates drawn from these surveys probably differ from the figures that would be obtained from a complete census, even if the same questionnaires and procedures were used. In the household survey, the amount of the differences can be expressed in terms of standard errors. The numerical value of a standard error depends upon the size of the sample, the results of the survey, and other factors. However, the numerical value is always such that the chances are approximately 68 out of 100 that an estimate based on the sample will differ by no more than the standard error
from the results of a complete census. The chances are approximately 90 out of 100 that an estimate based on the sample will differ by no more than 1.6 times the standard error from the results of a complete census. At approximately the 90 -percent level of confidence-the confidence limits used by bls in its analyses-the error for the monthly change in total employment is on the order of plus or minus 328,000 ; for total unemployment it is 220,000 ; and, for the overall unemployment rate, it is 0.19 percentage point. These figures do not mean that the sample results are off by these magnitudes but, rather, that the chances are approximately 90 out of 100 that the "true" level or rate would not be expected to differ from the estimates by more than these amounts.

Sampling errors for monthly surveys are reduced when the data are cumulated for several months, such as quarterly or annually. Also, as a general rule, the smaller the estimate, the larger the sampling error. Therefore, relatively speaking, the estimate of the size of the labor force is subject to less error than is the estimate of the number unemployed. And, among the unemployed, the sampling error for the jobless rate of adult men, for example, is much smaller than is the error for the jobless rate of teenagers. Specifically, the error on monthly change in the jobless rate for men is .26 percentage point; for teenagers, it is 1.25 percentage points.

In the establishment survey, estimates for the 2 most current months are based on incomplete returns; for this reason, these estimates are labeled preliminary in the tables. When all the returns in the sample have been received, the estimates are revised. In other words, data for the month of September are published in preliminary-form in October and November and in final form in December. To remove errors that build up over time, a comprehensive count of the employed is conducted each year. The results of this survey are used to establish new benchmarks-comprehensive counts of employment-against which month-to-month changes can be measured. The new benchmarks also incorporate changes in the classification of industries and allow for the formation of new establishments.

## Additional statistics and other information

In order to provide a broad view of the Nation's employment situation, BIS regularly publishes a wide variety of data in this news release. More comprehensive statistics are contained in Emplovment and Earnings, published each month by $\mathrm{BI} \varsigma$. It is available for $\$ 4.50$ per issue or $\$ 31.00$ per year from the U.S. Government Printing Office, Washington, D.C., 20204. A check or money order made out to the Superintendent of Documents must accompany all orders.

Emplovment and Earnings also provides approximations of the standard errors for the household survey data published in this release. For unemployment and other labor force categories, the standard errors appear in tables B through J of its "Explanatory Notes." Measures of the reliability of the data drawn from the establishment survey and the actual amounts of revision due to benchmark adjustments are provided in tables $M, O, P$, and $Q$ of that publication.

NOTE: Male Vietnam-era veterans are men who served in the Armed Forces between August 5. 1984 and May 7, 1975. Nonveterans are men who have never served in the Armed Forces; published data are limited to those 30 to 44 years of age, the group that most closely corresponds to the bulk of the Vietnam-era veteran population.

Data for 25- to 29 year-old veterans are no fonger shown in this table because the group is rapidly disappearing (into the $30-34$ age category) and the numbers remaining for some labor force categories are not large enough to warrant their continued publication.
