CAPACITY UTILIZATION

Manufacturing, Mining, Utilities, and Industrial Materials

November 16, 1983

Capacity utilization in manufacturing, mining, and utilities rose to 78.6 percent in October from 78.1 percent in September -- a somewhat more moderate advance than those recorded during the previous seven months. The operating rate for total manufacturing increased 0.6 percentage point to 78.9 percent, largely as a result of gains in activity within durable manufacturing. The mining industry operated at 71.6 percent of capacity in October -- up 0.7 percentage point -- while the rate for utilities declined.

Within manufacturing, industries producing metals, machinery, and aerospace and miscellaneous transportation equipment showed the largest gains in operating rates. The iron and steel industry increased its capacity use by about 3 percentage points, and rates for the machinery industries were up almost 1-1/2 percentage points. Despite these advances, operating rates in the steel and nonelectrical machinery industries are still well below their long-term averages. Capacity utilization at auto assembly plants was cut back to about 77-1/2 percent in October, apparently reflecting temporary shortages of essential parts. Nonetheless, for the motor vehicles and parts industry as a whole the operating rate was up a little in October because of increases in the production of trucks and parts.

Producers of industrial materials utilized 78.9 percent of capacity in October, up from 78.4 percent in September. The operating rate for producers of durable materials rose 1.0 percentage point in October. The rate for producers of nondurable materials increased only slightly, and the rate for producers of energy materials decreased.

Capacity Utilization: Summary

Definition. This release contains estimates of output, capacity, and capacity utilization for the nation's factories, mines, and electric and gas utilities. Estimates of actual output and capacity output are expressed as percentages of 1987 actual output. Estimates of capacity utilization are calculated as ratios, in percent, of the Federal Reserve's seasonally adjusted indexes of industrial production to the indexes of capacity. The capacity indexes are based on a variety of data, including capacity data in physical units, surveys of capacity growth and utilization rates, and estimates of capital stock growth. Instead of a formal definition of capacity the concept of practical capacity is applied, which is the greatest level of output that a plant can maintain within the framework of a realistic work pattern, taking account of normal downtime, and assuming sufficient availability of inputs to operate machinery and equipment in place. When the capacity indexes for individual industries are aggregated—for example to total manufacturing—no explicit account is taken of possible general equilibrium constraints such as emerging industry bottlenecks.

Groupings. Estimates of capacity and industrial production for manufacturing industries are aggregated to primary processing and advanced processing industries, to durable and non-durable manufacturing industries, and to total manufacturing. The mining, manufacturing, and utilities estimates aggregate to the total index. Industrial materials are items produced and used as inputs by manufacturing plants, mines, and utilities. Industrial materials include many of the items included in the primary processing grouping of manufacturing, as well as some of the output of the advanced processing industries, mines, and utilities—such as iron ore, crude oil, semiconductors, and electricity sold to industry.

Perspective. The historical highs and lows in capacity utilization shown in the tables above are specific to each series and did not all occur in the same month. Industrial plants usually operate at capacity utilization rates that are well below 100 percent; none of the broad aggregates has ever reached 100 percent. For mining, manufacturing, and utilities as a whole, and for total manufacturing, utilization rates as high as 90 percent have been exceeded only in wartime.

Revisions. The first estimates for a month are published about the 17th of the following month. These estimates may revise in each of the next three months as new data become available. After the fourth month no further revisions are undertaken until an annual or benchmark revision. The median of the revisions in the total manufacturing utilization rate between the first and fourth estimate is 0.3 of a percentage point; that is, in about half of the cases, the absolute value of the revision from the first to the fourth estimate is less than 0.3 of a percentage point.

Sources. The methodology used to estimate the series is discussed in *New Federal Reserve Measures of Capacity and Capacity Utilization*, Federal Reserve Bulletin, July 1983. Revised data from 1967-82 are included in the statistical supplement to the July 1983 capacity utilization release, which may be obtained from Publications Services, Board of Governors of the Federal Reserve System, Washington, D.C. 20551.

Rounding. The rounding algorithms applied to the capacity, output, and utilization rate series are independent. Aggregates are derived from unrounded detailed components.

Release schedule for 1983. Approximately 11 a.m. on August 17, September 16, October 17, November 16 and December 16.
